The \LaTeX3 Interfaces

The \LaTeX3 Project∗

Released 2020-05-15

Abstract

This is the reference documentation for the expl3 programming environment. The expl3 modules set up an experimental naming scheme for \LaTeX commands, which allow the \LaTeX programmer to systematically name functions and variables, and specify the argument types of functions.

The \TeX and \epsilon-\TeX primitives are all given a new name according to these conventions. However, in the main direct use of the primitives is not required or encouraged: the expl3 modules define an independent low-level \LaTeX3 programming language.

At present, the expl3 modules are designed to be loaded on top of \LaTeX2ε. In time, a \LaTeX3 format will be produced based on this code. This allows the code to be used in \LaTeX2ε packages now while a stand-alone \LaTeX3 is developed.

While expl3 is still experimental, the bundle is now regarded as broadly stable. The syntax conventions and functions provided are now ready for wider use. There may still be changes to some functions, but these will be minor when compared to the scope of expl3.

New modules will be added to the distributed version of expl3 as they reach maturity.

# Contents

## I Introduction to expl3 and this document
1. Naming functions and variables
   1.1 Terminological inexactitude
2. Documentation conventions
3. Formal language conventions which apply generally
4. \TeX concepts not supported by \LaTeX3

## II The \texttt{l3bootstrap} package: Bootstrap code
1. Using the \LaTeX3 modules

## III The \texttt{l3names} package: Namespace for primitives
1. Setting up the \LaTeX3 programming language

## IV The \texttt{l3basics} package: Basic definitions
1. No operation functions
2. Grouping material
3. Control sequences and functions
   3.1 Defining functions
   3.2 Defining new functions using parameter text
   3.3 Defining new functions using the signature
   3.4 Copying control sequences
   3.5 Deleting control sequences
   3.6 Showing control sequences
   3.7 Converting to and from control sequences
4. Analysing control sequences
5. Using or removing tokens and arguments
   5.1 Selecting tokens from delimited arguments
6. Predicates and conditionals
   6.1 Tests on control sequences
6.2 Primitive conditionals
7. Starting a paragraph
   7.1 Debugging support

Part I
Introduction to expl3 and this document

This document is intended to act as a comprehensive reference manual for the expl3 language. A general guide to the \LaTeX3 programming language is found in expl3.pdf.

1 Naming functions and variables

\LaTeX3 does not use @ as a “letter” for defining internal macros. Instead, the symbols _ and : are used in internal macro names to provide structure. The name of each function is divided into logical units using _, while : separates the name of the function from the argument specifier (“arg-spec”). This describes the arguments expected by the function. In most cases, each argument is represented by a single letter. The complete list of arg-spec letters for a function is referred to as the signature of the function.

Each function name starts with the module to which it belongs. Thus apart from a small number of very basic functions, all expl3 function names contain at least one underscore to divide the module name from the descriptive name of the function. For example, all functions concerned with comma lists are in module c-list and begin \clist_.

Every function must include an argument specifier. For functions which take no arguments, this will be blank and the function name will end :. Most functions take one or more arguments, and use the following argument specifiers:

N and n These mean no manipulation, of a single token for N and of a set of tokens given in braces for n. Both pass the argument through exactly as given. Usually, if you use a single token for an n argument, all will be well.

c This means csname, and indicates that the argument will be turned into a csname before being used. So \foo:c {ArgumentOne} will act in the same way as \foo:N \ArgumentOne.

V and v These mean value of variable. The V and v specifiers are used to get the content of a variable without needing to worry about the underlying \TeX structure containing the data. A V argument will be a single token (similar to N), for example \foo:V \MyVariable; on the other hand, using v a csname is constructed first, and then the value is recovered, for example \foo:v {MyVariable}.

o This means expansion once. In general, the V and v specifiers are favoured over o for recovering stored information. However, o is useful for correctly processing information with delimited arguments.

x The x specifier stands for exhaustive expansion: every token in the argument is fully expanded until only unexpandable ones remain. The \TeX \edef primitive carries out this type of expansion. Functions which feature an x-type argument are not expandable.

e The e specifier is in many respects identical to x, but with a very different implementation. Functions which feature an e-type argument may be expandable. The drawback is that e is extremely slow (often more than 200 times slower) in older engines, more precisely in non-Lua\TeX engines older than 2019.
The \texttt{f} specifier stands for \textit{full expansion}, and in contrast to \texttt{x} stops at the first non-expandable token (reading the argument from left to right) without trying to expand it. If this token is a ⟨space token⟩, it is gobbled, and thus won’t be part of the resulting argument. For example, when setting a token list variable (a macro used for storage), the sequence

\begin{verbatim}
\tl_set:Nn \l_mya_tl { A }
\tl_set:Nn \l_myb_tl { B }
\tl_set:Nf \l_mya_tl { \l_mya_tl \l_myb_tl }
\end{verbatim}

will leave \l_mya_tl with the content A\l_myb_tl, as A cannot be expanded and so terminates expansion before \l_myb_tl is considered.

\textbf{T and F} For logic tests, there are the branch specifiers \texttt{T} (\textit{true}) and \texttt{F} (\textit{false}). Both specifiers treat the input in the same way as \texttt{n} (no change), but make the logic much easier to see.

\textbf{p} The letter \texttt{p} indicates \TeX\ \textit{parameters}. Normally this will be used for delimited functions as \exp\texttt{3} provides better methods for creating simple sequential arguments.

\textbf{w} Finally, there is the \texttt{w} specifier for \textit{weird} arguments. This covers everything else, but mainly applies to delimited values (where the argument must be terminated by some specified string).

\textbf{D} The \texttt{D} specifier means \textit{do not use}. All of the \TeX\ primitives are initially \texttt{let} to a \texttt{D} name, and some are then given a second name. Only the kernel team should use anything with a \texttt{D} specifier!

Notice that the argument specifier describes how the argument is processed prior to being passed to the underlying function. For example, \texttt{\foo:c} will take its argument, convert it to a control sequence and pass it to \texttt{\foo:N}.

Variables are named in a similar manner to functions, but begin with a single letter to define the type of variable:

\begin{itemize}
  \item \texttt{c} Constant: global parameters whose value should not be changed.
  \item \texttt{g} Parameters whose value should only be set globally.
  \item \texttt{l} Parameters whose value should only be set locally.
\end{itemize}

Each variable name is then built up in a similar way to that of a function, typically starting with the module\textsuperscript{1} name and then a descriptive part. Variables end with a short identifier to show the variable type:

\begin{itemize}
  \item \texttt{clist} Comma separated list.
  \item \texttt{dim} “Rigid” lengths.
  \item \texttt{fp} Floating-point values;
  \item \texttt{int} Integer-valued count register.
\end{itemize}

\textsuperscript{1}The module names are not used in case of generic scratch registers defined in the data type modules, e.g., the \texttt{int} module contains some scratch variables called \texttt{\l_tmpa_int}, \texttt{\l_tmpb_int}, and so on. In such a case adding the module name up front to denote the module and in the back to indicate the type, as in \texttt{\l_int\_tmpa\_int} would be very unreadable.
muskip “Rubber” lengths for use in mathematics.

seq “Sequence”: a data-type used to implement lists (with access at both ends) and stacks.

skip “Rubber” lengths.

str String variables: contain character data.

tl Token list variables: placeholder for a token list.

Applying V-type or v-type expansion to variables of one of the above types is supported, while it is not supported for the following variable types:

bool Either true or false.

box Box register.

coffin A “box with handles” — a higher-level data type for carrying out box alignment operations.

flag Integer that can be incremented expandably.

fparray Fixed-size array of floating point values.

intarray Fixed-size array of integers.

ior/iow An input or output stream, for reading from or writing to, respectively.

prop Property list: analogue of dictionary or associative arrays in other languages.

regex Regular expression.

1.1 Terminological inexactitude

A word of warning. In this document, and others referring to the expl3 programming modules, we often refer to “variables” and “functions” as if they were actual constructs from a real programming language. In truth, TeX is a macro processor, and functions are simply macros that may or may not take arguments and expand to their replacement text. Many of the common variables are also macros, and if placed into the input stream will simply expand to their definition as well — a “function” with no arguments and a “token list variable” are almost the same.\footnote{TeXnically, functions with no arguments are \texttt{\long} while token list variables are not.} On the other hand, some “variables” are actually registers that must be initialised and their values set and retrieved with specific functions.

The conventions of the expl3 code are designed to clearly separate the ideas of “macros that contain data” and “macros that contain code”, and a consistent wrapper is applied to all forms of “data” whether they be macros or actually registers. This means that sometimes we will use phrases like “the function returns a value”, when actually we just mean “the macro expands to something”. Similarly, the term “execute” might be used in place of “expand” or it might refer to the more specific case of “processing in TeX’s stomach” (if you are familiar with the TeXbook parlance).

If in doubt, please ask; chances are we’ve been hasty in writing certain definitions and need to be told to tighten up our terminology.

2 Documentation conventions

This document is typeset with the experimental l3doc class; several conventions are used to help describe the features of the code. A number of conventions are used here to make the documentation clearer.

Each group of related functions is given in a box. For a function with a “user” name, this might read:

\ExplSyntaxOn ... \ExplSyntaxOff

The textual description of how the function works would appear here. The syntax of the function is shown in mono-spaced text to the right of the box. In this example, the function takes no arguments and so the name of the function is simply reprinted.

For programming functions, which use _ and : in their name there are a few additional conventions: If two related functions are given with identical names but different argument specifiers, these are termed variants of each other, and the latter functions are printed in grey to show this more clearly. They will carry out the same function but will take different types of argument:

\seq_new:N \seq_new:N \langle sequence \rangle
\seq_new:N \seq_new:c \langle sequence \rangle

When a number of variants are described, the arguments are usually illustrated only for the base function. Here, \langle sequence \rangle indicates that \seq_new:N expects the name of a sequence. From the argument specifier, \seq_new:c also expects a sequence name, but as a name rather than as a control sequence. Each argument given in the illustration should be described in the following text.

Fully expandable functions Some functions are fully expandable, which allows them to be used within an x-type or e-type argument (in plain TeX terms, inside an \edef or \expanded), as well as within an f-type argument. These fully expandable functions are indicated in the documentation by a star:

\cs_to_str:N \cs_to_str:N \langle cs \rangle

As with other functions, some text should follow which explains how the function works. Usually, only the star will indicate that the function is expandable. In this case, the function expects a \langle cs \rangle, shorthand for a \langle control sequence \rangle.

Restricted expandable functions A few functions are fully expandable but cannot be fully expanded within an f-type argument. In this case a hollow star is used to indicate this:

\seq_map_function:NN \seq_map_function:NN \langle seq \rangle \langle function \rangle

Conditional functions Conditional (if) functions are normally defined in three variants, with T, F and TF argument specifiers. This allows them to be used for different “true”/“false” branches, depending on which outcome the conditional is being used to test. To indicate this without repetition, this information is given in a shortened form:
The underlining and italic of \texttt{TF} indicates that three functions are available:

- \sys_if_engine_xetex:T
- \sys_if_engine_xetex:F
- \sys_if_engine_xetex:TF

Usually, the illustration will use the \texttt{TF} variant, and so both \texttt{(true code)} and \texttt{(false code)} will be shown. The two variant forms \texttt{T} and \texttt{F} take only \texttt{(true code)} and \texttt{(false code)}, respectively. Here, the star also shows that this function is expandable. With some minor exceptions, all conditional functions in the \texttt{expl3} modules should be defined in this way.

Variables, constants and so on are described in a similar manner:

\begin{verbatim}
\l_tmpa_tl
\end{verbatim}

A short piece of text will describe the variable: there is no syntax illustration in this case.

In some cases, the function is similar to one in \LaTeX2ε or plain \TeX. In these cases, the text will include an extra “\texttt{\LaTeXhackers note}” section:

\begin{verbatim}
\token_to_str:N
\end{verbatim}

The normal description text.

\texttt{\LaTeXhackers note}: Detail for the experienced \TeX or \LaTeX2ε programmer. In this case, it would point out that this function is the \TeX primitive \texttt{\string}.

Changes to behaviour When new functions are added to \texttt{expl3}, the date of first inclusion is given in the documentation. Where the documented behaviour of a function changes after it is first introduced, the date of the update will also be given. This means that the programmer can be sure that any release of \texttt{expl3} after the date given will contain the function of interest with expected behaviour as described. Note that changes to code internals, including bug fixes, are not recorded in this way unless they impact on the expected behaviour.

3 Formal language conventions which apply generally

As this is a formal reference guide for \LaTeX3 programming, the descriptions of functions are intended to be reasonably “complete”. However, there is also a need to avoid repetition. Formal ideas which apply to general classes of function are therefore summarised here.

For tests which have a \texttt{TF} argument specification, the test if evaluated to give a logically \texttt{TRUE} or \texttt{FALSE} result. Depending on this result, either the \texttt{(true code)} or the \texttt{(false code)} will be left in the input stream. In the case where the test is expandable, and a predicate (\_p) variant is available, the logical value determined by the test is left in the input stream: this will typically be part of a larger logical construct.
4 \texttt{\LaTeX} concepts not supported by \LaTeXe\texttt{3}

The \TeX{} concept of an \texttt{\textbackslash outer} macro is \textit{not supported} at all by \LaTeXe\texttt{3}. As such, the functions provided here may break when used on top of \LaTeXe\texttt{2\epsilon} if \texttt{\textbackslash outer} tokens are used in the arguments.
Part II
The \texttt{l3bootstrap} package
Bootstrap code

1 Using the L\TeX\n3 modules

The modules documented in \texttt{source3} are designed to be used on top of \LaTeX\n2\texttt{\varepsilon} and are loaded all as one with the usual \texttt{\usepackage{expl3}} or \texttt{\RequirePackage{expl3}} instructions. These modules will also form the basis of the \LaTeX\n3 format, but work in this area is incomplete and not included in this documentation at present.

As the modules use a coding syntax different from standard \LaTeX\n2\texttt{\varepsilon} it provides a few functions for setting it up.

\texttt{\ExplSyntaxOn ⟨code⟩ \ExplSyntaxOff}

The \texttt{\ExplSyntaxOn} function switches to a category code régime in which spaces are ignored and in which the colon (:) and underscore (_) are treated as ‘letters’, thus allowing access to the names of code functions and variables. Within this environment, ~ is used to input a space. The \texttt{\ExplSyntaxOff} reverts to the document category code régime.

\texttt{\ProvidesExplPackage \ProvidesExplClass \ProvidesExplFile}

Updated: 2011-08-13

\texttt{\GetIdInfo $Id: ⟨SVN info field⟩$ \{(description)\}}

Updated: 2012-06-04

Contains all information from a SVN field. Spaces are not ignored in these fields. The information pieces are stored in separate control sequences with \texttt{\ExplFileName} for the part of the file name leading up to the period, \texttt{\ExplFileDate} for date, \texttt{\ExplFileVersion} for version and \texttt{\ExplFileDescription} for the description.

To summarize: Every single package using this syntax should identify itself using one of the above methods. Special care is taken so that every package or class file loaded with \texttt{\RequirePackage} or similar are loaded with usual \LaTeX\n2\texttt{\varepsilon} category codes and the \LaTeX\n3 category code scheme is reloaded when needed afterwards. See implementation for details. If you use the \texttt{\GetIdInfo} command you can use the information when loading a package with

\texttt{\ProvidesExplPackage\{(\ExplFileName)\}}

\texttt{\{(\ExplFileDate)\{\ExplFileVersion\}\{\ExplFileDescription\}}}
Part III

The l3names package

Namespace for primitives

1 Setting up the \LaTeX3 programming language

This module is at the core of the \LaTeX3 programming language. It performs the following tasks:

- defines new names for all \TeX primitives;
- switches to the category code régime for programming;
- provides support settings for building the code as a \TeX format.

This module is entirely dedicated to primitives, which should not be used directly within \LaTeX3 code (outside of “kernel-level” code). As such, the primitives are not documented here: *The \TeXbook, \TeX by Topic* and the manuals for pdf\TeX, \Xe\TeX, Lua\TeX, \micro\TeX and \up\TeX should be consulted for details of the primitives. These are named `\text⟨name⟩:D`, typically based on the primitive’s ⟨name⟩ in pdf\TeX and omitting a leading `pdf` when the primitive is not related to pdf output.
Part IV

The \texttt{l3basics} package

Basic definitions

As the name suggest this package holds some basic definitions which are needed by most or all other packages in this set.

Here we describe those functions that are used all over the place. With that we mean functions dealing with the construction and testing of control sequences. Furthermore the basic parts of conditional processing are covered; conditional processing dealing with specific data types is described in the modules specific for the respective data types.

1 No operation functions

\begin{verbatim}
\prg_do_nothing: \* \prg_do_nothing:
An expandable function which does nothing at all: leaves nothing in the input stream after a single expansion.
\end{verbatim}

\begin{verbatim}
\scan_stop: \scan_stop:
A non-expandable function which does nothing. Does not vanish on expansion but produces no typeset output.
\end{verbatim}

2 Grouping material

\begin{verbatim}
\group_begin: \group_begin:
\group_end: \group_end:
These functions begin and end a group for definition purposes. Assignments are local to groups unless carried out in a global manner. (A small number of exceptions to this rule will be noted as necessary elsewhere in this document.) Each \texttt{\group_begin}: must be matched by a \texttt{\group_end}:; although this does not have to occur within the same function. Indeed, it is often necessary to start a group within one function and finish it within another, for example when seeking to use non-standard category codes.
\end{verbatim}

\begin{verbatim}
\group_insert_after:N \group_insert_after:N \texttt{(token)}
Adds \texttt{(token)} to the list of \texttt{(tokens)} to be inserted when the current group level ends. The list of \texttt{(tokens)} to be inserted is empty at the beginning of a group: multiple applications of \texttt{\group_insert_after:N} may be used to build the inserted list one \texttt{\text{(token)}} at a time. The current group level may be closed by a \texttt{\group_end}: function or by a token with category code 2 (close-group), namely a \texttt{)} if standard category codes apply.
\end{verbatim}
3 Control sequences and functions

As \TeX{} is a macro language, creating new functions means creating macros. At point of use, a function is replaced by the replacement text (“code”) in which each parameter in the code (#1, #2, etc.) is replaced the appropriate arguments absorbed by the function. In the following, ⟨code⟩ is therefore used as a shorthand for “replacement text”.

Functions which are not “protected” are fully expanded inside an x expansion. In contrast, “protected” functions are not expanded within x expansions.

3.1 Defining functions

Functions can be created with no requirement that they are declared first (in contrast to variables, which must always be declared). Declaring a function before setting up the code means that the name chosen is checked and an error raised if it is already in use. The name of a function can be checked at the point of definition using the \texttt{\cs_new...} functions: this is recommended for all functions which are defined for the first time.

There are three ways to define new functions. All classes define a function to expand to the substitution text. Within the substitution text the actual parameters are substituted for the formal parameters (#1, #2, ...).

new Create a new function with the \texttt{new} scope, such as \texttt{\cs_new:Npn}. The definition is global and results in an error if it is already defined.

set Create a new function with the \texttt{set} scope, such as \texttt{\cs_set:Npn}. The definition is restricted to the current \TeX{} group and does not result in an error if the function is already defined.

gset Create a new function with the \texttt{gset} scope, such as \texttt{\cs_gset:Npn}. The definition is global and does not result in an error if the function is already defined.

Within each set of scope there are different ways to define a function. The differences depend on restrictions on the actual parameters and the expandability of the resulting function.

nopar Create a new function with the \texttt{nopar} restriction, such as \texttt{\cs_set_nopar:Npn}. The parameter may not contain \texttt{\par} tokens.

protected Create a new function with the \texttt{protected} restriction, such as \texttt{\cs_set_protected:Npn}. The parameter may contain \texttt{\par} tokens but the function will not expand within an x-type or e-type expansion.

Finally, the functions in Subsections 3.2 and 3.3 are primarily meant to define base functions only. Base functions can only have the following argument specifiers:

\texttt{N} and \texttt{n} No manipulation.

\texttt{T} and \texttt{F} Functionally equivalent to \texttt{n} (you are actually encouraged to use the family of \texttt{\prg_new_conditional:} functions described in Section 1).

\texttt{p} and \texttt{w} These are special cases.

The \texttt{\cs_new:} functions below (and friends) do not stop you from using other argument specifiers in your function names, but they do not handle expansion for you. You should define the base function and then use \texttt{\cs_generate_variant:Nn} to generate custom variants as described in Section 2.
### 3.2 Defining new functions using parameter text

\begin{align*}
\text{\texttt{\textbackslash cs\_new\_Npn \ (function) \ (parameters) \ \{\text{code}\}}}
\end{align*}

Creates \texttt{\texttt{\textbackslash (function) to expand to \texttt{(code) as replacement text. Within the \texttt{(code), the parameters \texttt{(#1, #2, etc.) will be replaced by those absorbed by the function. The definition is global and an error results if the \texttt{(function) is already defined.}}}}}

\begin{align*}
\text{\texttt{\textbackslash cs\_new\_nopar\_Npn \ (function) \ (parameters) \ \{\text{code}\}}}
\end{align*}

Creates \texttt{\texttt{\textbackslash (function) to expand to \texttt{(code) as replacement text. Within the \texttt{(code), the parameters \texttt{(#1, #2, etc.) will be replaced by those absorbed by the function. When the \texttt{(function) is used the \texttt{(parameters)} absorbed cannot contain \texttt{\textbackslash par} tokens. The definition is global and an error results if the \texttt{(function) is already defined.}}}}}

\begin{align*}
\text{\texttt{\textbackslash cs\_new\_protected\_Npn \ (function) \ (parameters) \ \{\text{code}\}}}
\end{align*}

Creates \texttt{\texttt{\textbackslash (function) to expand to \texttt{(code) as replacement text. Within the \texttt{(code), the \texttt{(parameters)} \texttt{(#1, #2, etc.) will be replaced by those absorbed by the function. The \texttt{(function) will not expand within an \texttt{x-type argument. The definition is global and an error results if the \texttt{(function) is already defined.}}}}}

\begin{align*}
\text{\texttt{\textbackslash cs\_new\_protected\_nopar\_Npn \ (function) \ (parameters) \ \{\text{code}\}}}
\end{align*}

Creates \texttt{\texttt{\textbackslash (function) to expand to \texttt{(code) as replacement text. Within the \texttt{(code), the \texttt{(parameters)} \texttt{(#1, #2, etc.) will be replaced by those absorbed by the function. The \texttt{(function) will not expand within an \texttt{x-type or e-type argument. The definition is global and an error results if the \texttt{(function) is already defined.}}}}}

\begin{align*}
\text{\texttt{\textbackslash cs\_set\_Npn \ (function) \ (parameters) \ \{\text{code}\}}}
\end{align*}

Sets \texttt{\texttt{\textbackslash (function) to expand to \texttt{(code) as replacement text. Within the \texttt{(code), the \texttt{(parameters)} \texttt{(#1, #2, etc.) will be replaced by those absorbed by the function. The assignment of a meaning to the \texttt{(function) is restricted to the current \TeX{} group level.}}}}}

\begin{align*}
\text{\texttt{\textbackslash cs\_set\_nopar\_Npn \ (function) \ (parameters) \ \{\text{code}\}}}
\end{align*}

Sets \texttt{\texttt{\textbackslash (function) to expand to \texttt{(code) as replacement text. Within the \texttt{(code), the \texttt{(parameters)} \texttt{(#1, #2, etc.) will be replaced by those absorbed by the function. When the \texttt{(function) is used the \texttt{(parameters)} absorbed cannot contain \texttt{\textbackslash par} tokens. The assignment of a meaning to the \texttt{(function) is restricted to the current \TeX{} group level.}}}}}

\begin{align*}
\text{\texttt{\textbackslash cs\_set\_protected\_Npn \ (function) \ (parameters) \ \{\text{code}\}}}
\end{align*}

Sets \texttt{\texttt{\textbackslash (function) to expand to \texttt{(code) as replacement text. Within the \texttt{(code), the \texttt{(parameters)} \texttt{(#1, #2, etc.) will be replaced by those absorbed by the function. The assignment of a meaning to the \texttt{(function) is restricted to the current \TeX{} group level. The \texttt{(function) will not expand within an \texttt{x-type or e-type argument.}}}}}

11
3.3 Defining new functions using the signature

\cs_new:Nn
\cs_new:(cn|nx|cx)

Creates \texttt{(function)} to expand to \texttt{(code)} as replacement text. Within the \texttt{(code)}, the number of \texttt{(parameters)} is detected automatically from the function signature. These \texttt{(parameters)} \texttt{(#1, #2, etc.)} will be replaced by those absorbed by the function. The definition is global and an error results if the \texttt{(function)} is already defined.
\newcommand*{\cs}{\texttt{\textbackslash cs}}
\newcommand*{\cs_protected}{\texttt{\textbackslash cs\_protected}}
\newcommand*{\cs_new_protected}{\texttt{\textbackslash cs\_new\_protected}}
\newcommand*{\cs_new_protected_nopar}{\texttt{\textbackslash cs\_new\_protected\_nopar}}
\newcommand*{\cs_set}{\texttt{\textbackslash cs\_set}}
\newcommand*{\cs_set_protected}{\texttt{\textbackslash cs\_set\_protected}}
\newcommand*{\cs_set_nopar}{\texttt{\textbackslash cs\_set\_nopar}}
\newcommand*{\cs_new_nopar}{\texttt{\textbackslash cs\_new\_nopar}}

\newcommand*{\function}{\texttt{\textbackslash function}}
\newcommand*{\code}{\texttt{\textbackslash code}}
\newcommand*{\par}{\texttt{\textbackslash par}}

\cs_new_protected:Nn \function \{ \code \}
\cs_set_protected:Nn \function \{ \code \}

Creates (function) to expand to (code) as replacement text. Within the (code), the
number of (parameters) is detected automatically from the function signature. These
(parameters) (#1, #2, etc.) will be replaced by those absorbed by the function. When the
(function) is used the (parameters) absorbed cannot contain \par tokens. The definition
is global and an error results if the (function) is already defined.

\cs_new_protected:Nn \function \{ \code \}
\cs_set_protected:Nn \function \{ \code \}

Creates (function) to expand to (code) as replacement text. Within the (code), the
number of (parameters) (\#1, \#2, etc.) will be replaced by those absorbed by the function. The
(function) will not expand within an x-type argument. The definition is global and an
error results if the (function) is already defined.

\cs_new_protected_nopar:Nn \function \{ \code \}
\cs_set_protected_nopar:Nn \function \{ \code \}

Creates (function) to expand to (code) as replacement text. Within the (code), the
number of (parameters) (\#1, \#2, etc.) will be replaced by those absorbed by the function. When the
(function) will not expand within an x-type or e-type argument. The definition is global and an
error results if the (function) is already defined.

\cs_set:Nn \function \{ \code \}
\cs_set_nopar:Nn \function \{ \code \}

Sets (function) to expand to (code) as replacement text. Within the (code), the number of
(parameters) is detected automatically from the function signature. These (parameters)
(#1, #2, etc.) will be replaced by those absorbed by the function. The assignment of a
meaning to the (function) is restricted to the current \TeX{} group level.

\cs_set_nopar:Nn \function \{ \code \}
\cs_set_protected:Nn \function \{ \code \}

Sets (function) to expand to (code) as replacement text. Within the (code), the number of
(parameters) is detected automatically from the function signature. These (parameters)
(#1, #2, etc.) will be replaced by those absorbed by the function. When the (function)
is used the (parameters) absorbed cannot contain \par tokens. The assignment of a
meaning to the (function) is restricted to the current \TeX{} group level.

\cs_set_protected:Nn \function \{ \code \}
\cs_set_protected_nopar:Nn \cs_set_protected_nopar:cn\#1cx \cs_set_protected_nopar:cn\#1\#2cx

Sets \texttt{function} to expand to \texttt{code} as replacement text. Within the \texttt{code}, the number of \texttt{parameters} is detected automatically from the function signature. These \texttt{parameters} (\#1, \#2, etc.) will be replaced by those absorbed by the function. When the \texttt{function} is used the \texttt{parameters} absorbed cannot contain \texttt{par} tokens. The \texttt{function} will not expand within an \texttt{x}-type or \texttt{e}-type argument. The assignment of a meaning to the \texttt{function} is restricted to the current \TeX{} group level.

\cs_gset_nopar:Nn \cs_gset_nopar:cn\#1cx
\cs_gset_nopar:cn\#1\#2cx

Sets \texttt{function} to expand to \texttt{code} as replacement text. Within the \texttt{code}, the number of \texttt{parameters} is detected automatically from the function signature. These \texttt{parameters} (\#1, \#2, etc.) will be replaced by those absorbed by the function. The assignment of a meaning to the \texttt{function} is global.

\cs_gset_nopar:Nn \cs_gset_nopar:cn\#1cx
\cs_gset_nopar:cn\#1\#2cx

Sets \texttt{function} to expand to \texttt{code} as replacement text. Within the \texttt{code}, the number of \texttt{parameters} is detected automatically from the function signature. These \texttt{parameters} (\#1, \#2, etc.) will be replaced by those absorbed by the function. When the \texttt{function} is used the \texttt{parameters} absorbed cannot contain \texttt{par} tokens. The assignment of a meaning to the \texttt{function} is global.

\cs_gset_protected_nopar:Nn \cs_gset_protected_nopar:cn\#1cx
\cs_gset_protected_nopar:cn\#1\#2cx

Sets \texttt{function} to expand to \texttt{code} as replacement text. Within the \texttt{code}, the number of \texttt{parameters} is detected automatically from the function signature. These \texttt{parameters} (\#1, \#2, etc.) will be replaced by those absorbed by the function. The \texttt{function} will not expand within an \texttt{x}-type argument. The assignment of a meaning to the \texttt{function} is global.

\cs_gset_protected_nopar:Nn \cs_gset_protected_nopar:cn\#1cx
\cs_gset_protected_nopar:cn\#1\#2cx
\cs_gset_protected_nopar:cn\#1\#2\#3cx
\cs_gset_protected_nopar:cn\#1\#2\#3\#4cx

Sets \texttt{function} to expand to \texttt{code} as replacement text. Within the \texttt{code}, the number of \texttt{parameters} is detected automatically from the function signature. These \texttt{parameters} (\#1, \#2, etc.) will be replaced by those absorbed by the function. When the \texttt{function} is used the \texttt{parameters} absorbed cannot contain \texttt{par} tokens. The \texttt{function} will not expand within an \texttt{x}-type or \texttt{e}-type argument. The assignment of a meaning to the \texttt{function} is global.

\cs_generate_from_arg_count:NNNn \cs_generate_from_arg_count:NNNn \texttt{function} \texttt{creator} \{\texttt{number}\} \texttt{code}

Uses the \texttt{creator} function (which should have signature \texttt{Npnn}, for example \texttt{cs_new:Npn}) to define a \texttt{function} which takes \texttt{number} arguments and has \texttt{code} as replacement text. The \texttt{number} of arguments is an integer expression, evaluated as detailed for \texttt{\int_eval:n}.

Updated: 2012-01-14
3.4 Copying control sequences

Control sequences (not just functions as defined above) can be set to have the same meaning using the functions described here. Making two control sequences equivalent means that the second control sequence is a copy of the first (rather than a pointer to it). Thus the old and new control sequence are not tied together: changes to one are not reflected in the other.

In the following text “cs” is used as an abbreviation for “control sequence”.

\begin{verbatim}
\cs_new_eq:NN \cs_new_eq:NN \cs_new_eq:(Nc|cN|cc)
\end{verbatim}

Globally creates \textit{control sequence}_1 and sets it to have the same meaning as \textit{control sequence}_2 or \textit{token}. The second control sequence may subsequently be altered without affecting the copy.

\begin{verbatim}
\cs_set_eq:NN \cs_set_eq:NN \cs_set_eq:(Nc|cN|cc)
\end{verbatim}

Sets \textit{control sequence}_1 to have the same meaning as \textit{control sequence}_2 (or \textit{token}). The second control sequence may subsequently be altered without affecting the copy. The assignment of a meaning to the \textit{control sequence}_1 is restricted to the current \TeX group level.

\begin{verbatim}
\cs_gset_eq:NN \cs_gset_eq:NN \cs_gset_eq:(Nc|cN|cc)
\end{verbatim}

Globally sets \textit{control sequence}_1 to have the same meaning as \textit{control sequence}_2 (or \textit{token}). The second control sequence may subsequently be altered without affecting the copy. The assignment of a meaning to the \textit{control sequence}_1 is not restricted to the current \TeX group level: the assignment is global.

3.5 Deleting control sequences

There are occasions where control sequences need to be deleted. This is handled in a very simple manner.

\begin{verbatim}
\cs_undefine:N \cs_undefine:c
\end{verbatim}

Sets \textit{control sequence} to be globally undefined.

3.6 Showing control sequences

\begin{verbatim}
\cs_meaning:N \cs_meaning:c
\end{verbatim}

This function expands to the \textit{meaning} of the \textit{control sequence} control sequence. For a macro, this includes the \textit{replacement text}.

\TeXhackers note: This is \TeX’s \texttt{\meaning} primitive. For tokens that are not control sequences, it is more logical to use \texttt{\token_to_meaning:N}. The \texttt{c} variant correctly reports undefined arguments.
\cs_show:N \cs_show:c
Displays the definition of the \textit{(control sequence)} on the terminal.

\textbf{\TeX\hackers note:} This is similar to the \TeX\ primitive \texttt{\show}, wrapped to a fixed number of characters per line.

\cs_log:N \cs_log:c
Writes the definition of the \textit{(control sequence)} in the log file. See also \texttt{\cs_show:N} which displays the result in the terminal.

3.7 Converting to and from control sequences

\use:c \{\langle control sequence name\rangle\}
Expands the \textit{(control sequence name)} until only characters remain, and then converts this into a control sequence. This process requires two expansions. As in other \texttt{c}-type arguments the \textit{(control sequence name)} must, when fully expanded, consist of character tokens, typically a mixture of category code 10 (space), 11 (letter) and 12 (other).

\textbf{\TeX\hackers note:} Protected macros that appear in a \texttt{c}-type argument are expanded despite being protected; \texttt{\exp_not:n} also has no effect. An internal error occurs if non-characters or active characters remain after full expansion, as the conversion to a control sequence is not possible.

As an example of the \texttt{\use:c} function, both
\begin{verbatim}
\use:c { a b c }
\end{verbatim}
and
\begin{verbatim}
\tl_new:N \l_my_tl
\tl_set:Nn \l_my_tl { a b c }
\use:c { \tl_use:N \l_my_tl }
\end{verbatim}
would be equivalent to
\begin{verbatim}
\abc
\end{verbatim}
after two expansions of \texttt{\use:c}.

\cs_if_exist_use:N \cs_if_exist_use:c \cs_if_exist_use:NTF \cs_if_exist_use:cTF
Tests whether the \textit{(control sequence)} is currently defined according to the conditional \texttt{\cs_if_exist:NTF} (whether as a function or another control sequence type), and if it is inserts the \textit{(control sequence)} into the input stream followed by the \textit{(true code)}. Otherwise the \textit{(false code)} is used.
\cs:w * \cs:w \{control sequence name\} \cs_end:

Converts the given \{control sequence name\} into a single control sequence token. This process requires one expansion. The content for \{control sequence name\} may be literal material or from other expandable functions. The \{control sequence name\} must, when fully expanded, consist of character tokens which are not active: typically of category code 10 (space), 11 (letter) or 12 (other), or a mixture of these.

**TeXhackers note:** These are the TeX primitives \csname and \endcsname.

As an example of the \cs:w and \cs_end: functions, both

\cs:w a b c \cs_end:

and

\tl_new:N \l_my_tl
\tl_set:Nn \l_my_tl { a b c }
\cs:w \tl_use:N \l_my_tl \cs_end:

would be equivalent to

\abc

after one expansion of \cs:w.

\cs_to_str:N * \cs_to_str:N \{control sequence\}

Converts the given \{control sequence\} into a series of characters with category code 12 (other), except spaces, of category code 10. The result does not include the current escape token, contrarily to \token_to_str:N. Full expansion of this function requires exactly 2 expansion steps, and so an \x-type or \e-type expansion, or two \o-type expansions are required to convert the \{control sequence\} to a sequence of characters in the input stream. In most cases, an \f-expansion is correct as well, but this loses a space at the start of the result.

4 Analyzing control sequences

\cs_split_function:N * \cs_split_function:N \{function\}

Splits the \{function\} into the \{name\} (i.e. the part before the colon) and the \{signature\} (i.e. after the colon). This information is then placed in the input stream in three parts: the \{name\}, the \{signature\} and a logic token indicating if a colon was found (to differentiate variables from function names). The \{name\} does not include the escape character, and both the \{name\} and \{signature\} are made up of tokens with category code 12 (other).

The next three functions decompose TeX macros into their constituent parts: if the \{token\} passed is not a macro then no decomposition can occur. In the latter case, all three functions leave \scan_stop: in the input stream.
\cs_prefix_spec:N \cs_prefix_spec:N \token

If the \token is a macro, this function leaves the applicable \TeX prefixes in input stream as a string of tokens of category code 12 (with spaces having category code 10). Thus for example

\cs_set:Npn \next:nn #1#2 { x #1~y #2 }
\cs_prefix_spec:N \next:nn

leaves \long in the input stream. If the \token is not a macro then \scan_stop: is left in the input stream.

\TeXhackers note: The prefix can be empty, \long, \protect or \protected\long with backslash replaced by the current escape character.

\cs_argument_spec:N \cs_argument_spec:N \token

If the \token is a macro, this function leaves the primitive \TeX argument specification in input stream as a string of character tokens of category code 12 (with spaces having category code 10). Thus for example

\cs_set:Npn \next:nn #1#2 { x #1 y #2 }
\cs_argument_spec:N \next:nn

leaves #1#2 in the input stream. If the \token is not a macro then \scan_stop: is left in the input stream.

\TeXhackers note: If the argument specification contains the string \texttt{->}, then the function produces incorrect results.

\cs_replacement_spec:N \cs_replacement_spec:N \token

If the \token is a macro, this function leaves the replacement text in input stream as a string of character tokens of category code 12 (with spaces having category code 10). Thus for example

\cs_set:Npn \next:nn #1#2 { x #1-y #2 }
\cs_replacement_spec:N \next:nn

leaves x#1\texttt{y#2} in the input stream. If the \token is not a macro then \scan_stop: is left in the input stream.

\TeXhackers note: If the argument specification contains the string \texttt{->}, then the function produces incorrect results.

5 Using or removing tokens and arguments

Tokens in the input can be read and used or read and discarded. If one or more tokens are wrapped in braces then when absorbing them the outer set is removed. At the same time, the category code of each token is set when the token is read by a function (if it
is read more than once, the category code is determined by the situation in force when first function absorbs the token).

As illustrated, these functions absorb between one and four arguments, as indicated by the argument specifier. The braces surrounding each argument are removed and the remaining tokens are left in the input stream. The category code of these tokens is also fixed by this process (if it has not already been by some other absorption). All of these functions require only a single expansion to operate, so that one expansion of

\[\text{\use:n \{ abc \} \{ \{ def \} \}}\]

results in the input stream containing

\[abc \{ def \}\]

i.e. only the outer braces are removed.

\textbf{\LaTeX hackers note:} The \texttt{\use:n} function is equivalent to \LaTeX{} 2ε’s \texttt{\@firstofone}.

These functions absorb two arguments from the input stream. The function \texttt{\use:i:nn} discards the second argument, and leaves the content of the first argument in the input stream. \texttt{\use:ii:nn} discards the first argument and leaves the content of the second argument in the input stream. The category code of these tokens is also fixed (if it has not already been by some other absorption). A single expansion is needed for the functions to take effect.

\textbf{\LaTeX hackers note:} These are equivalent to \LaTeX{} 2ε’s \texttt{\@firstoftwo} and \texttt{\@secondoftwo}.

These functions absorb three arguments from the input stream. The function \texttt{\use:i:nnn} discards the second and third arguments, and leaves the content of the first argument in the input stream. \texttt{\use:ii:nnn} and \texttt{\use:iii:nnn} work similarly, leaving the content of second or third arguments in the input stream, respectively. The category code of these tokens is also fixed (if it has not already been by some other absorption). A single expansion is needed for the functions to take effect.

These functions absorb four arguments from the input stream. The function \texttt{\use:i:nnnn} discards the second, third and fourth arguments, and leaves the content of the first argument in the input stream. \texttt{\use:ii:nnnn}, \texttt{\use:iii:nnnn} and \texttt{\use:iv:nnnn} work similarly, leaving the content of second, third or fourth arguments in the input stream, respectively. The category code of these tokens is also fixed (if it has not already been by some other absorption). A single expansion is needed for the functions to take effect.

This function absorbs three arguments and leaves the content of the first and second in the input stream. The category code of these tokens is also fixed (if it has not already been by some other absorption). A single expansion is needed for the function to take effect. An example:

\use_i_ii:nnn \{ abc \} \{ \{ def \} \} \{ ghi \}

results in the input stream containing

\texttt{abc \{ def \}}

\textit{i.e.} the outer braces are removed and the third group is removed.

This function absorbs two arguments and leaves the content of the second and first in the input stream. The category code of these tokens is also fixed (if it has not already been by some other absorption). A single expansion is needed for the function to take effect.

\texttt{\use_ii_i:nn \{ arg1 \} \{ arg2 \}}

These functions absorb between one and nine groups from the input stream, leaving nothing on the resulting input stream. These functions work after a single expansion. One or more of the \texttt{n} arguments may be an unbraced single token (\textit{i.e.} an \texttt{N} argument).

\textbf{\texttt{\use_none:n}}

\texttt{\use_none:nn}

\texttt{\use_none:nnn}

\texttt{\use_none:nnnn}

\texttt{\use_none:nnnnn}

\texttt{\use_none:nnnnnn}

\texttt{\use_none:nnnnnnn}

\texttt{\use_none:nnnnnnnn}

\texttt{\use_none:nnnnnnnnn}

\texttt{\use:e \{ expandable tokens \}}

Fully expands the \texttt{\{token list\}} in an \texttt{x}-type manner, \textit{but} the function remains fully expandable, and parameter character (usually \texttt{#}) need not be doubled.

\textbf{\texttt{\use:e}} is a wrapper around the primitive \texttt{\expanded} where it is available: it requires two expansions to complete its action. When \texttt{\expanded} is not available this function is very slow.

\texttt{\use:x \{ expandable tokens \}}

Fully expands the \texttt{\{expandable tokens\}} and inserts the result into the input stream at the current location. Any hash characters (#) in the argument must be doubled.

5.1 Selecting tokens from delimited arguments

A different kind of function for selecting tokens from the token stream are those that use delimited arguments.
Absorb the \textit{balanced text} from the input stream delimited by the marker given in the function name, leaving nothing in the input stream.

Absorb the \textit{balanced text} from the input stream delimited by the marker given in the function name, leaving \textit{inserted tokens} in the input stream for further processing.

6 Predicates and conditionals

\LaTeX{} has three concepts for conditional flow processing:

**Branching conditionals** Functions that carry out a test and then execute, depending on its result, either the code supplied as the \textit{true code} or the \textit{false code}. These arguments are denoted with \texttt{T} and \texttt{F}, respectively. An example would be

\begin{verbatim}
\cs_if_free:cTF {abc} {\langle true code \rangle} {\langle false code \rangle}
\end{verbatim}

a function that turns the first argument into a control sequence (since it's marked as \texttt{c}) then checks whether this control sequence is still free and then depending on the result carries out the code in the second argument (true case) or in the third argument (false case).

These type of functions are known as “conditionals”: whenever a \texttt{TF} function is defined it is usually accompanied by \texttt{T} and \texttt{F} functions as well. These are provided for convenience when the branch only needs to go a single way. Package writers are free to choose which types to define but the kernel definitions always provide all three versions.

Important to note is that these branching conditionals with \textit{true code} and/or \textit{false code} are always defined in a way that the code of the chosen alternative can operate on following tokens in the input stream.

These conditional functions may or may not be fully expandable, but if they are expandable they are accompanied by a “predicate” for the same test as described below.

**Predicates** “Predicates” are functions that return a special type of boolean value which can be tested by the boolean expression parser. All functions of this type are expandable and have names that end with \texttt{p} in the description part. For example,

\begin{verbatim}
\cs_if_free_p:N {N}
\end{verbatim}

would be a predicate function for the same type of test as the conditional described above. It would return “true” if its argument (a single token denoted by \texttt{N}) is still free for definition. It would be used in constructions like
For each predicate defined, a “branching conditional” also exists that behaves like a conditional described above.

**Primitive conditionals** There is a third variety of conditional, which is the original concept used in plain TeX and \LaTeX. Their use is discouraged in expl3 (although still used in low-level definitions) because they are more fragile and in many cases require more expansion control (hence more code) than the two types of conditionals described above.

\begin{verbatim}
\c_true_bool
\c_false_bool
\end{verbatim}

Constants that represent \texttt{true} and \texttt{false}, respectively. Used to implement predicates.

### 6.1 Tests on control sequences

\begin{verbatim}
\cs_if_eq_p:NN * \cs_if_eq_p:NN {true code} {false code}
\cs_if_eq_p:NNTF * \cs_if_eq_p:NNTF {true code} {false code}
\end{verbatim}

Compares the definition of two \texttt{(control sequences)} and is logically \texttt{true} if they are the same, \textit{i.e.} if they have exactly the same definition when examined with \texttt{\cs_show:N}.

\begin{verbatim}
\cs_if_exist_p:N * \cs_if_exist:p:NNTF * \cs_if_exist:N * \cs_if_exist:cTF *
\end{verbatim}

Tests whether the \texttt{(control sequence)} is currently defined (whether as a function or another control sequence type). Any definition of \texttt{(control sequence)} other than \texttt{\relax} evaluates as true.

\begin{verbatim}
\cs_if_free_p:N * \cs_if_free:p:NNTF * \cs_if_free:N * \cs_if_free:cTF *
\end{verbatim}

Tests whether the \texttt{(control sequence)} is currently free to be defined. This test is \texttt{false} if the \texttt{(control sequence)} currently exists (as defined by \texttt{\cs_if_exist:N}).

### 6.2 Primitive conditionals

The e-Tex engine itself provides many different conditionals. Some expand whatever comes after them and others don’t. Hence the names for these underlying functions often contains a :w part but higher level functions are often available. See for instance \texttt{\int_compare_p:nNn} which is a wrapper for \texttt{\if_int_compare:w}.

Certain conditionals deal with specific data types like boxes and fonts and are described there. The ones described below are either the universal conditionals or deal with control sequences. We prefix primitive conditionals with \texttt{\if_}.  

22
\if_true: \if_true: \else: (false code) \fi:
\if_false: \if_false: \else: (false code) \fi:
\else: \reverse_if:N (primitive conditional)
\fi:
\reverse_if:N \if_true: always executes (true code), while \if_false: always executes (false code).
\reverse_if:N reverses any two-way primitive conditional. \else: and \fi: delimit the branches of the conditional. The function \or: is documented in l3int and used in case switches.

\TeXhackers note: These are equivalent to their corresponding \TeX: primitive conditionals; \reverse_if:N is \TeX: \unless.

\if_meaning:w \if_meaning:w (arg_1) (arg_2) (true code) \else: (false code) \fi:
\if_meaning:w executes (true code) when (arg_1) and (arg_2) are the same, otherwise it executes (false code). (arg_1) and (arg_2) could be functions, variables, tokens; in all cases the unexpanded definitions are compared.

\TeXhackers note: This is \TeX: \ifx.

\if:w \if:w (token_1) (token_2) (true code) \else: (false code) \fi:
\if_charcode:w \if_charcode:w (token_1) (token_2) (true code) \else: (false code) \fi:
\if_catcode:w \if_catcode:w (token_1) (token_2) (true code) \else: (false code) \fi:
These conditionals expand any following tokens until two unexpandable tokens are left. If you wish to prevent this expansion, prefix the token in question with \exp_not:N. \if_catcode:w tests if the category codes of the two tokens are the same whereas \if:w tests if the character codes are identical. \if_charcode:w is an alternative name for \if:w.

\if_cs_exist:N \if_cs_exist:w (cs) (true code) \else: (false code) \fi:
\if_cs_exist:w (tokens) \cs_end: (true code) \else: (false code) \fi:
Check if (cs) appears in the hash table or if the control sequence that can be formed from (tokens) appears in the hash table. The latter function does not turn the control sequence in question into \scan_stop:! This can be useful when dealing with control sequences which cannot be entered as a single token.

\if_mode_horizontal: \if_mode_horizontal: (true code) \else: (false code) \fi:
\if_mode_vertical: \if_mode_vertical: (true code) \else: (false code) \fi:
\if_mode_math: \if_mode_math: (true code) \else: (false code) \fi:
\if_mode_inner: \if_mode_inner: (true code) \else: (false code) \fi:
Execute (true code) if currently in horizontal mode, otherwise execute (false code). Similar for the other functions.
7 Starting a paragraph

\mode_leave_vertical: 
Ensures that \TeX is not in vertical (inter-paragraph) mode. In horizontal or math mode this command has no effect, in vertical mode it switches to horizontal mode, and inserts a box of width \parindent, followed by the \everypar token list.

\TeXhackers note: This results in the contents of the \everypar token register being inserted, after \mode_leave_vertical: is complete. Notice that in contrast to the \LaTeX2ε \leavevmode approach, no box is used by the method implemented here.

7.1 Debugging support

\debug_on:n \debug_off:n 
Turn on and off within a group various debugging code, some of which is also available as expl3 load-time options. The items that can be used in the ⟨list⟩ are

- check-declarations that checks all expl3 variables used were previously declared and that local/global variables (based on their name or on their first assignment) are only locally/globally assigned;
- check-expressions that checks integer, dimension, skip, and muskip expressions are not terminated prematurely;
- deprecation that makes soon-to-be-deprecated commands produce errors;
- log-functions that logs function definitions;
- all that does all of the above.

Providing these as switches rather than options allows testing code even if it relies on other packages: load all other packages, call \debug_on:n, and load the code that one is interested in testing. These functions can only be used in \LaTeX2ε package mode loaded with enable-debug or another option implying it.

\debug_suspend: ... \debug_resume: 
Suppress (locally) errors and logging from debug commands, except for the deprecation errors or warnings. These pairs of commands can be nested. This can be used around pieces of code that are known to fail checks, if such failures should be ignored. See for instance l3coffins.
Part V

The \l3expan\ package

Argument expansion

This module provides generic methods for expanding \TeX\ arguments in a systematic manner. The functions in this module all have prefix `exp`.

Not all possible variations are implemented for every base function. Instead only those that are used within the \LaTeX\ kernel or otherwise seem to be of general interest are implemented. Consult the module description to find out which functions are actually defined. The next section explains how to define missing variants.

1 Defining new variants

The definition of variant forms for base functions may be necessary when writing new functions or when applying a kernel function in a situation that we haven’t thought of before.

Internally preprocessing of arguments is done with functions of the form `\exp_`. They all look alike, an example would be `\exp_args:NNo`. This function has three arguments, the first and the second are a single token, while the third argument should be given in braces. Applying `\exp_args:NNo` expands the content of third argument once before any expansion of the first and second arguments. If `\seq_gpush:No` was not defined it could be coded in the following way:

\begin{verbatim}
\exp_args:NNo \seq_gpush:Nn
\g_file_name_stack
\{ \l_tmpa_tl \}
\end{verbatim}

In other words, the first argument to `\exp_args:NNo` is the base function and the other arguments are preprocessed and then passed to this base function. In the example the first argument to the base function should be a single token which is left unchanged while the second argument is expanded once. From this example we can also see how the variants are defined. They just expand into the appropriate `\exp_` function followed by the desired base function, e.g.

\begin{verbatim}
\cs_generate_variant:Nn \seq_gpush:Nn \seq_gpush:No \{ No \}
\end{verbatim}

results in the definition of `\seq_gpush:No`

\begin{verbatim}
\cs_new:Npn \seq_gpush:No \{ \exp_args:NNo \seq_gpush:Nn \}
\end{verbatim}

Providing variants in this way in style files is safe as the `\cs_generate_variant:Nn` function will only create new definitions if there is not already one available. Therefore adding such definition to later releases of the kernel will not make such style files obsolete.

The steps above may be automated by using the function `\cs_generate_variant:` described next.
2 Methods for defining variants

We recall the set of available argument specifiers.

- $N$ is used for single-token arguments while $c$ constructs a control sequence from its name and passes it to a parent function as an $N$-type argument.

- Many argument types extract or expand some tokens and provide it as an $n$-type argument, namely a braced multiple-token argument: $V$ extracts the value of a variable, $v$ extracts the value from the name of a variable, $n$ uses the argument as it is, $o$ expands once, $f$ expands fully the front of the token list, $e$ and $x$ expand fully all tokens (differences are explained later).

- A few odd argument types remain: $T$ and $F$ for conditional processing, otherwise identical to $n$-type arguments, $p$ for the parameter text in definitions, $w$ for arguments with a specific syntax, and $D$ to denote primitives that should not be used directly.
This function is used to define argument-specifier variants of the \textit{parent control sequence} for \LaTeX\ code-level macros. The \textit{parent control sequence} is first separated into the \textit{base name} and \textit{original argument specifier}. The comma-separated list of \textit{variant argument specifiers} is then used to define variants of the \textit{original argument specifier} if these are not already defined. For each \textit{variant} given, a function is created that expands its arguments as detailed and passes them to the \textit{parent control sequence}. So for example
\begin{verbatim}
\cs_set:Npn \foo:Nn #1#2 { code here }
\cs_generate_variant:Nn \foo:Nn { c }
\end{verbatim}
creates a new function \foo:cn which expands its first argument into a control sequence name and passes the result to \foo:Nn. Similarly
\begin{verbatim}
\cs_generate_variant:Nn \foo:cn \foo:Nn { NV , cV }
\end{verbatim}
generates the functions \foo:NV and \foo:cV in the same way. The \texttt{\texttt{\texttt{cs\_generate\_variant}}:\texttt{Nn}} function can only be applied if the \textit{parent control sequence} is already defined. If the \textit{parent control sequence} is protected or if the \textit{variant} involves any \texttt{x} argument, then the \textit{variant control sequence} is also protected. The \textit{variant} is created globally, as is any \texttt{\texttt{\exp\_args}}:\texttt{N(\texttt{variant})} function needed to carry out the expansion.

Only \texttt{n} and \texttt{N} arguments can be changed to other types. The only allowed changes are
\begin{itemize}
  \item \texttt{c} variant of an \texttt{N} parent;
  \item \texttt{o}, \texttt{V}, \texttt{v}, \texttt{f}, \texttt{e}, or \texttt{x} variant of an \texttt{n} parent;
  \item \texttt{N}, \texttt{n}, \texttt{T}, \texttt{F}, or \texttt{p} argument unchanged.
\end{itemize}

This means the \textit{parent} of a \textit{variant} form is always unambiguous, even in cases where both an \texttt{n}-type parent and an \texttt{N}-type parent exist, such as for \texttt{\texttt{\texttt{\texttt{\tl\_count}}}:\texttt{n}} and \texttt{\texttt{\texttt{\texttt{\tl\_count}}}:\texttt{N}}.

For backward compatibility it is currently possible to make \texttt{n}, \texttt{o}, \texttt{V}, \texttt{v}, \texttt{f}, \texttt{e}, or \texttt{x}-type variants of an \texttt{N}-type argument or \texttt{N} or \texttt{c}-type variants of an \texttt{n}-type argument. Both are deprecated. The first because passing more than one token to an \texttt{N}-type argument will typically break the parent function’s code. The second because programmers who use that most often want to access the value of a variable given its name, hence should use a \texttt{V}-type or \texttt{v}-type variant instead of \texttt{c}-type. In those cases, using the lower-level \texttt{\exp\_args}:\texttt{No} or \texttt{\exp\_args}:\texttt{Nc} functions explicitly is preferred to defining confusing variants.

\section{Introducing the variants}

The \texttt{V} type returns the value of a register, which can be one of \texttt{tl}, \texttt{clist}, \texttt{int}, \texttt{skip}, \texttt{dim}, \texttt{muskip}, or built-in \TeX\ registers. The \texttt{v} type is the same except it first creates a control sequence out of its argument before returning the value.

In general, the programmer should not need to be concerned with expansion control. When simply using the content of a variable, functions with a \texttt{V} specifier should be used. For those referred to by (cs)name, the \texttt{v} specifier is available for the same purpose. Only
when specific expansion steps are needed, such as when using delimited arguments, should the lower-level functions with \texttt{o} specifiers be employed.

The \texttt{e} type expands all tokens fully, starting from the first. More precisely the expansion is identical to that of \TeX's \texttt{message} (in particular \texttt{#} needs not be doubled). It was added in May 2018. In recent enough engines (starting around 2019) it relies on the primitive \texttt{expanded} hence is fast. In older engines it is very much slower. As a result it should only be used in performance critical code if typical users will have a recent installation of the \TeX\ ecosystem.

The \texttt{x} type expands all tokens fully, starting from the first. In contrast to \texttt{e}, all macro parameter characters \texttt{#} must be doubled, and omitting this leads to low-level errors. In addition this type of expansion is not expandable, namely functions that have \texttt{x} in their signature do not themselves expand when appearing inside \texttt{x} or \texttt{e} expansion.

The \texttt{f} type is so special that it deserves an example. It is typically used in contexts where only expandable commands are allowed. Then \texttt{x}-expansion cannot be used, and \texttt{f}-expansion provides an alternative that expands the front of the token list as much as can be done in such contexts. For instance, say that we want to evaluate the integer expression $3 + 4$ and pass the result 7 as an argument to an expandable function \texttt{example:n}. For this, one should define a variant using $\texttt{\cs_generate_variant:Nn \example:n { f }}$, then do

$$\texttt{\example:f \{ \int_eval:n \{ 3 + 4 \} \}}$$

Note that \texttt{x}-expansion would also expand \texttt{\int_eval:n} fully to its result 7, but the variant \texttt{\example:x} cannot be expandable. Note also that \texttt{o}-expansion would not expand \texttt{\int_eval:n} fully to its result since that function requires several expansions. Besides the fact that \texttt{x}-expansion is protected rather than expandable, another difference between \texttt{f}-expansion and \texttt{x}-expansion is that \texttt{f}-expansion expands tokens from the beginning and stops as soon as a non-expandable token is encountered, while \texttt{x}-expansion continues expanding further tokens. Thus, for instance

$$\texttt{\example:f \{ \int_eval:n \{ 1 + 2 \} , \int_eval:n \{ 3 + 4 \} \}}$$

results in the call

$$\texttt{\example:n \{ 3 , \int_eval:n \{ 3 + 4 \} \}}$$

while using \texttt{\example:x} or \texttt{\example:e} instead results in

$$\texttt{\example:n \{ 3 , 7 \}}$$

at the cost of being protected (for \texttt{x} type) or very much slower in old engines (for \texttt{e} type). If you use \texttt{f} type expansion in conditional processing then you should stick to using \texttt{TF} type functions only as the expansion does not finish any \texttt{if...fi: itself!}

It is important to note that both \texttt{f-} and \texttt{o-type} expansion are concerned with the expansion of tokens from left to right in their arguments. In particular, \texttt{o-type} expansion applies to the first \textit{token} in the argument it receives: it is conceptually similar to

$$\texttt{\exp_after:wN \texttt{<base function>} \exp_after:wN \{ \texttt{<argument>} \}}$$

At the same time, \texttt{f-type} expansion stops at the \textit{first} non-expandable token. This means for example that both

$$\texttt{\tl_set:Nn \\tl_tmpa_tl \{ \{ \texttt{\g_tmpb_tl} \} \}}$$
and

\tl_set:Nf \l_tmpa_tl \{ \{ \g_tmpb_tl \} \}

leave \g_tmpb_tl unchanged: \{ is the first token in the argument and is non-expandable.

It is usually best to keep the following in mind when using variant forms.

- Variants with x-type arguments (that are fully expanded before being passed to the n-type base function) are never expandable even when the base function is. Such variants cannot work correctly in arguments that are themselves subject to expansion. Consider using f or e expansion.

- In contrast, e expansion (full expansion, almost like x except for the treatment of #) does not prevent variants from being expandable (if the base function is). The drawback is that e expansion is very much slower in old engines (before 2019). Consider using f expansion if that type of expansion is sufficient to perform the required expansion, or x expansion if the variant will not itself need to be expandable.

- Finally f expansion only expands the front of the token list, stopping at the first non-expandable token. This may fail to fully expand the argument.

When speed is essential (for functions that do very little work and whose variants are used numerous times in a document) the following considerations apply because internal functions for argument expansion come in two flavours, some faster than others.

- Arguments that might need expansion should come first in the list of arguments.

- Arguments that should consist of single tokens N, c, V, or v should come first among these.

- Arguments that appear after the first multi-token argument n, f, e, or o require slightly slower special processing to be expanded. Therefore it is best to use the optimized functions, namely those that contain only N, c, V, and v, and, in the last position, o, f, e, with possible trailing N or n or T or F, which are not expanded. Any x-type argument causes slightly slower processing.

4 Manipulating the first argument

These functions are described in detail: expansion of multiple tokens follows the same rules but is described in a shorter fashion.

\exp_args:Nc \exp_args:cc

This function absorbs two arguments (the (function) name and the (tokens)). The (tokens) are expanded until only characters remain, and are then turned into a control sequence. The result is inserted into the input stream after reinsertion of the (function). Thus the (function) may take more than one argument: all others are left unchanged.

The :cc variant constructs the (function) name in the same manner as described for the (tokens).

\TeXhackers note: Protected macros that appear in a c-type argument are expanded despite being protected; \exp_not:n also has no effect. An internal error occurs if non-characters or active characters remain after full expansion, as the conversion to a control sequence is not possible.
This function absorbs two arguments (the \textit{function} name and the \textit{tokens}). The \textit{tokens} are expanded once, and the result is inserted in braces into the input stream \textit{after} reinsertion of the \textit{function}. Thus the \textit{function} may take more than one argument: all others are left unchanged.

T\TeX{} hackers note: Protected macros that appear in a v-type argument are expanded despite being protected; \texttt{\exp_not:n} also has no effect. An internal error occurs if non-characters or active characters remain after full expansion, as the conversion to a control sequence is not possible.

This function absorbs two arguments (the \textit{function} name and the \textit{tokens}) and exhaustively expands the \textit{tokens}. The result is inserted in braces into the input stream \textit{after} reinsertion of the \textit{function}. Thus the \textit{function} may take more than one argument: all others are left unchanged.

T\TeX{} hackers note: This relies on the \texttt{\expanded} primitive when available (in Lua\TeX{} and starting around 2019 in other engines). Otherwise it uses some fall-back code that is very much slower. As a result it should only be used in performance-critical code if typical users have a recent installation of the \TeX{} ecosystem.
This function absorbs two arguments (the \textit{(function)} name and the \textit{(tokens)}) and exhaustively expands the \textit{(tokens)}. The result is inserted in braces into the input stream \textit{after} reinsertion of the \textit{(function)}. Thus the \textit{(function)} may take more than one argument: all others are left unchanged.

## 5 Manipulating two arguments

These optimized functions absorb three arguments and expand the second and third as detailed by their argument specifier. The first argument of the function is then the next item on the input stream, followed by the expansion of the second and third arguments.

These functions absorb three arguments and expand the second and third as detailed by their argument specifier. The first argument of the function is then the next item on the input stream, followed by the expansion of the second and third arguments. These functions need slower processing.

These functions absorb three arguments and expand the second and third as detailed by their argument specifier. The first argument of the function is then the next item on the input stream, followed by the expansion of the second and third arguments. These functions are not expandable due to their \textit{x}-type argument.
6 Manipulating three arguments

\exp_args:NNNo \langle token_1 \rangle \langle token_2 \rangle \langle token_3 \rangle \{\langle tokens \rangle\}

These optimized functions absorb four arguments and expand the second, third and fourth as detailed by their argument specifier. The first argument of the function is then the next item on the input stream, followed by the expansion of the second argument, \textit{etc.}

\exp_args:NNcf \langle token_1 \rangle \langle token_2 \rangle \{\langle tokens \rangle\}

These functions absorb four arguments and expand the second, third and fourth as detailed by their argument specifier. The first argument of the function is then the next item on the input stream, followed by the expansion of the second argument, \textit{etc.} These functions need slower processing.

\exp_args:NNx \langle token_1 \rangle \langle token_2 \rangle \{\langle tokens_1 \rangle\} \{\langle tokens_2 \rangle\}

These functions absorb four arguments and expand the second, third and fourth as detailed by their argument specifier. The first argument of the function is then the next item on the input stream, followed by the expansion of the second argument, \textit{etc.}
7 Unbraced expansion

These functions absorb the number of arguments given by their specification, carry out
the expansion indicated and leave the results in the input stream, with the last argument
not surrounded by the usual braces. Of these, the :Nno, :Noo, :Nfo and :NnNo variants
need slower processing.

**\TeXhackers note:** As an optimization, the last argument is unbraced by some of those
functions before expansion. This can cause problems if the argument is empty: for instance,
\exp_last_unbraced:Nf \foo_bar:w { } \q_stop leads to an infinite loop, as the quark is
f-
expanded.

\begin{itemize}
\item \exp_last_unbraced:No
\item \exp_last_unbraced:NV
\item \exp_last_unbraced:Ne
\item \exp_last_unbraced:Nf
\item \exp_last_unbraced:NNo
\item \exp_last_unbraced:NNV
\item \exp_last_unbraced:NNf
\item \exp_last_unbraced:Nco
\item \exp_last_unbraced:NcV
\item \exp_last_unbraced:Nno
\item \exp_last_unbraced:Noo
\item \exp_last_unbraced:Nfo
\item \exp_last_unbraced:NNNo
\item \exp_last_unbraced:NNNV
\item \exp_last_unbraced:NNf
\item \exp_last_unbraced:NnNo
\item \exp_last_unbraced:NNNo
\item \exp_last_unbraced:NNf
\end{itemize}

\textbf{Updated: 2018-05-15}

\begin{itemize}
\item \exp_last_unbraced:Nx
\item \exp_last_unbraced:Nx \langle \text{function} \rangle \{ \langle \text{tokens} \rangle \}
\end{itemize}

This function fully expands the \langle \text{tokens} \rangle and leaves the result in the input stream after
reinsertion of the \langle \text{function} \rangle. This function is not expandable.

\begin{itemize}
\item \exp_last_two_unbraced:Noo
\item \exp_last_two_unbraced:Noo \langle \text{token} \rangle \{ \langle \text{tokens} \rangle \}
\end{itemize}

This function absorbs three arguments and expands the second and third once. The first
argument of the function is then the next item on the input stream, followed by the
expansion of the second and third arguments, which are not wrapped in braces. This
function needs special (slower) processing.

\begin{itemize}
\item \exp_after:wN
\item \exp_after:wN \langle \text{token} \rangle \langle \text{token} \rangle
\end{itemize}

Carries out a single expansion of \langle \text{token} \rangle (which may consume arguments) prior to the
expansion of \langle \text{token} \rangle. If \langle \text{token} \rangle has no expansion (for example, if it is a character) then
it is left unchanged. It is important to notice that \langle \text{token} \rangle may be any single token, including
group-opening and -closing tokens \{ or \} assuming normal \TeX category codes).
Unless specifically required this should be avoided: expansion should be carried out using
an appropriate argument specifier variant or the appropriate \exp_arg:N function.

**\TeXhackers note:** This is the \TeX primitive \texttt{\expandafter} renamed.

8 Preventing expansion

Despite the fact that the following functions are all about preventing expansion, they’re
designed to be used in an expandable context and hence are all marked as being ‘expand-
able’ since they themselves disappear after the expansion has completed.

\exp_not:N \exp_not:N \langle \text{token} \rangle

Prevents expansion of the \langle \text{token} \rangle in a context where it would otherwise be expanded, for example an x-type argument or the first token in an o or e or f argument.

\textbf{\LaTeX}hackers note: This is the \LaTeX \noexpand primitive. It only prevents expansion. At the beginning of an f-type argument, a space \langle \text{token} \rangle is removed even if it appears as \exp_not:N \c_space_token. In an x-expanding definition (\cs_new:Npx), a macro parameter introduces an argument even if it appears as \exp_not:N \# 1. This differs from \exp_not:n.

\exp_not:c \exp_not:c \{ \langle \text{tokens} \rangle \}

Expands the \langle \text{tokens} \rangle until only characters remain, and then converts this into a control sequence. Further expansion of this control sequence is then inhibited using \exp_not:N.

\textbf{\LaTeX}hackers note: Protected macros that appear in a c-type argument are expanded despite being protected; \exp_not:n also has no effect. An internal error occurs if non-characters or active characters remain after full expansion, as the conversion to a control sequence is not possible.

\exp_not:n \exp_not:n \{ \langle \text{tokens} \rangle \}

Prevents expansion of the \langle \text{tokens} \rangle in an e or x-type argument. In all other cases the \langle \text{tokens} \rangle continue to be expanded, for example in the input stream or in other types of arguments such as c, f, v. The argument of \exp_not:n must be surrounded by braces.

\textbf{\LaTeX}hackers note: This is the e-\LaTeX \unexpanded primitive. In an x-expanding definition (\cs_new:Npx), \exp_not:n \{\#1\} is equivalent to \#1 rather than to \#1, namely it inserts the two characters \# and 1. In an e-type argument \exp_not:n \{\#\} is equivalent to \#, namely it inserts the character \#.

\exp_not:o \exp_not:o \{ \langle \text{tokens} \rangle \}

Expands the \langle \text{tokens} \rangle once, then prevents any further expansion in x-type or e-type arguments using \exp_not:n.

\exp_not:V \exp_not:V \langle \text{variable} \rangle

Recovers the content of the \langle \text{variable} \rangle, then prevents expansion of this material in x-type or e-type arguments using \exp_not:n.
\exp_not:v * \exp_not:v \{\langle\text{tokens}\rangle\}

Expands the \langle\text{tokens}\rangle until only characters remains, and then converts this into a control sequence which should be a \langle\text{variable}\rangle name. The content of the \langle\text{variable}\rangle is recovered, and further expansion in x-type or e-type arguments is prevented using \exp_not:n.

\textbf{TeXhackers note:} Protected macros that appear in a v-type argument are expanded despite being protected; \exp_not:n also has no effect. An internal error occurs if non-characters or active characters remain after full expansion, as the conversion to a control sequence is not possible.

\exp_not:e * \exp_not:e \{\langle\text{tokens}\rangle\}

Expands \langle\text{tokens}\rangle exhaustively, then protects the result of the expansion (including any tokens which were not expanded) from further expansion in e or x-type arguments using \exp_not:n. This is very rarely useful but is provided for consistency.

\exp_not:f * \exp_not:f \{\langle\text{tokens}\rangle\}

Expands \langle\text{tokens}\rangle fully until the first unexpandable token is found (if it is a space it is removed). Expansion then stops, and the result of the expansion (including any tokens which were not expanded) is protected from further expansion in x-type or e-type arguments using \exp_not:n.

\exp_stop_f: * \foo_bar:f \{\langle\text{tokens}\rangle\exp_stop_f:\langle\text{more tokens}\rangle\}

This function terminates an f-type expansion. Thus if a function \foo_bar:f starts an f-type expansion and all of \langle\text{tokens}\rangle are expandable \exp_stop_f: terminates the expansion of tokens even if \langle\text{more tokens}\rangle are also expandable. The function itself is an implicit space token. Inside an x-type expansion, it retains its form, but when typeset it produces the underlying space (\uni2423).

9 \textbf{Controlled expansion}

The expl3 language makes all efforts to hide the complexity of \TeX expansion from the programmer by providing concepts that evaluate/expand arguments of functions prior to calling the “base” functions. Thus, instead of using many \expandafter calls and other trickery it is usually a matter of choosing the right variant of a function to achieve a desired result.

Of course, deep down \TeX is using expansion as always and there are cases where a programmer needs to control that expansion directly; typical situations are basic data manipulation tools. This section documents the functions for that level. These commands are used throughout the kernel code, but we hope that outside the kernel there will be little need to resort to them. Instead the argument manipulation methods document above should usually be sufficient.

While \exp_after:wN expands one token (out of order) it is sometimes necessary to expand several tokens in one go. The next set of commands provide this functionality. Be aware that it is absolutely required that the programmer has full control over the tokens to be expanded, i.e., it is not possible to use these functions to expand unknown input as part of \langle\text{expandable-tokens}\rangle as that will break badly if unexpandable tokens are encountered in that place!
\exp:w * \exp:w \langle expandable-tokens \rangle \exp_end:
\exp_end: *

Expands \langle expandable-tokens \rangle \exp_end: at which point expansion stops.
The full expansion of \langle expandable-tokens \rangle has to be empty. If any token in \langle expandable tokens \rangle or any token generated by expanding the tokens therein is not expandable the expansion will end prematurely and as a result \exp_end: will be misinterpreted later on.\footnote{Due to the implementation you might get the character in position 0 in the current font (typically ‘‘’’) in the output without any error message!}

In typical use cases the \exp_end: is hidden somewhere in the replacement text of \langle expandable-tokens \rangle rather than being on the same expansion level than \exp:w, e.g., you may see code such as

\exp:w \@@_case:NnTF #1 {#2} { } { }

where somewhere during the expansion of \@@_case:NnTF the \exp_end: gets generated.

\TeXhackers note: The current implementation uses \romannumeral hence ignores space tokens and explicit signs + and - in the expansion of \langle expandable-tokens \rangle, but this should not be relied upon.

\exp:w * \exp_end_continue_f:w * \exp_end_continue_f:w \langle further-tokens \rangle

Expands \langle expandable-tokens \rangle until reaching \exp_end_continue_f:w at which point expansion continues as an f-type expansion expanding \langle further-tokens \rangle until an unexpandable token is encountered (or the f-type expansion is explicitly terminated by \exp_stop_f:]. As with all f-type expansions a space ending the expansion gets removed. The full expansion of \langle expandable-tokens \rangle has to be empty. If any token in \langle expandable-tokens \rangle or any token generated by expanding the tokens therein is not expandable the expansion will end prematurely and as a result \exp_end_continue_f:w will be misinterpreted later on.\footnote{In this particular case you may get a character into the output as well as an error message.}

In typical use cases \langle expandable-tokens \rangle contains no tokens at all, e.g., you will see code such as

\exp_after:wN \exp:w \exp_end_continue_f:w \#2

where the \exp_after:wN triggers an f-expansion of the tokens in \#2. For technical reasons this has to happen using two tokens (if they would be hidden inside another command \exp_after:wN would only expand the command but not trigger any additional f-expansion).

You might wonder why there are two different approaches available, after all the effect of

\exp:w \langle expandable-tokens \rangle \exp_end:

\exp:w \exp_end_continue_f:w \langle expandable-tokens \rangle \exp_stop_f:

The reason is simply that the first approach is slightly faster (one less token to parse and less expansion internally) so in places where such performance really matters and where we want to explicitly stop the expansion at a defined point the first form is preferable.
The difference to \texttt{\textbackslash exp\_end\_continue\_f:w} is that we first we pick up an argument which is then returned to the input stream. If \texttt{\textbackslash further\_tokens} starts with space tokens then these space tokens are removed while searching for the argument. If it starts with a brace group then the braces are removed. Thus such spaces or braces will not terminate the \texttt{f}-type expansion.

## 10 Internal functions

\begin{verbatim}
\cs_new:Npn \exp_args:Ncof { \::c \::o \::f \::: }
\cs_new:Npn \exp_last_unbraced:Nno { \::n \::o_unbraced \::: }
\end{verbatim}

Internal forms for the base expansion types. These names do \textit{not} conform to the general \LaTeX{}X3 approach as this makes them more readily visible in the log and so forth. They should not be used outside this module.

\begin{verbatim}
\cs_new:Npn \exp_last_unbraced:Nno { \::n \::o_unbraced \::: }
\end{verbatim}

Internal forms for the expansion types which leave the terminal argument unbraced. These names do \textit{not} conform to the general \LaTeX{}X3 approach as this makes them more readily visible in the log and so forth. They should not be used outside this module.
Part VI
The \texttt{\textsc{l3quark}} package

Quarks

Two special types of constants in \LaTeX{}3 are “quarks” and “scan marks”. By convention all constants of type quark start out with \texttt{\textbackslash q\_}, and scan marks start with \texttt{\textbackslash s\_}. 

1 Quarks

Quarks are control sequences that expand to themselves and should therefore \textit{never} be executed directly in the code. This would result in an endless loop!

They are meant to be used as delimiter in weird functions, the most common use case being the 'stop token' (\textit{i.e.} \texttt{\textbackslash q\_\textunderscore\textunderscore\texttoast{}}). For example, when writing a macro to parse a user-defined date

\begin{verbatim}
\date\tt{parse:n} {19/June/1981}
\end{verbatim}

one might write a command such as

\begin{verbatim}
\cs_new:Npn \date\tt{parse:n} #1 { \date\tt{parse:aux:w} #1 \q_stop }
\cs_new:Npn \date\tt{parse:aux:w} #1 / #2 / #3 \q_stop
{ <do something with the date> }
\end{verbatim}

Quarks are sometimes also used as error return values for functions that receive erroneous input. For example, in the function \texttt{\prop\tt{get:NnN}} to retrieve a value stored in some key of a property list, if the key does not exist then the return value is the quark \texttt{\textbackslash q\_no\_value}. As mentioned above, such quarks are extremely fragile and it is imperative when using such functions that code is carefully written to check for pathological cases to avoid leakage of a quark into an uncontrolled environment.

Quarks also permit the following ingenious trick when parsing tokens: when you pick up a token in a temporary variable and you want to know whether you have picked up a particular quark, all you have to do is compare the temporary variable to the quark using \texttt{\tl\_if\_eq:NNTF}. A set of special quark testing functions is set up below. All the quark testing functions are expandable although the ones testing only single tokens are much faster. An example of the quark testing functions and their use in recursion can be seen in the implementation of \texttt{\clist\_map\_function:NN}.

2 Defining quarks

\begin{verbatim}
\quark\new:N \langle quark \rangle
\end{verbatim}

Creates a new \texttt{(quark)} which expands only to \texttt{(quark)}. The \texttt{(quark)} is defined globally, and an error message is raised if the name was already taken.

\begin{verbatim}
\q\_stop
\end{verbatim}

Used as a marker for delimited arguments, such as

\begin{verbatim}
\cs_set:Npn \tmp:w \#1\#2 \q\_stop \{\#1\}
\end{verbatim}
\q_mark

Used as a marker for delimited arguments when \q_stop is already in use.

\q_nil

Quark to mark a null value in structured variables or functions. Used as an end delimiter when this may itself need to be tested (in contrast to \q_stop, which is only ever used as a delimiter).

\q_no_value

A canonical value for a missing value, when one is requested from a data structure. This is therefore used as a “return” value by functions such as \prop_get:NnN if there is no data to return.

3 Quark tests

The method used to define quarks means that the single token (N) tests are faster than the multi-token (n) tests. The latter should therefore only be used when the argument can definitely take more than a single token.

\quark_if_nil_p:N *
\quark_if_nil:NTF *

\quark_if_nil_p:n *
\quark_if_nil:p:(o|V) *
\quark_if_nil:n:TF *

Tests if the \langle token \rangle is equal to \q_nil.

\quark_if_no_value_p:N *
\quark_if_no_value:p:c *
\quark_if_no_value:n:TF *
\quark_if_no_value:c:TF *

\quark_if_no_value_p:n *
\quark_if_no_value:p:(o|V) *
\quark_if_no_value:n:TF *
\quark_if_no_value:c:TF *

Tests if the \langle token list \rangle contains only \q_nil (distinct from \langle token list \rangle being empty or containing \q_nil plus one or more other tokens).

4 Recursion

This module provides a uniform interface to intercepting and terminating loops as when one is doing tail recursion. The building blocks follow below and an example is shown in Section 5.

\q_recursion_tail

This quark is appended to the data structure in question and appears as a real element there. This means it gets any list separators around it.
This quark is added after the data structure. Its purpose is to make it possible to terminate the recursion at any point easily.

Tests if \( \langle \text{token} \rangle \) contains only the marker \( \texttt{\textbackslash q-recursion\_tail} \), and if so uses \texttt{\textbackslash use\_none\_delimit\_by\_q-recursion\_stop:w} to terminate the recursion that this belongs to. The recursion input must include the marker tokens \( \texttt{\textbackslash q-recursion\_tail} \) and \( \texttt{\textbackslash q-recursion\_stop} \) as the last two items.

Tests if the \( \langle \text{token list} \rangle \) contains only \( \texttt{\textbackslash q-recursion\_tail} \), and if so uses \texttt{\textbackslash use\_i\_delimit\_by\_q-recursion\_stop:w} to terminate the recursion that this belongs to. The recursion input must include the marker tokens \( \texttt{\textbackslash q-recursion\_tail} \) and \( \texttt{\textbackslash q-recursion\_stop} \) as the last two items. The \( \langle \text{insertion} \rangle \) code is then added to the input stream after the recursion has ended.

Tests if \( \langle \text{token list} \rangle \) contains only \( \texttt{\textbackslash q-recursion\_tail} \), and if so terminates the recursion using \( \langle \text{type} \rangle \texttt{\_map\_break:} \). The recursion end should be marked by \( \texttt{\textbackslash prg\_break\_point:Nn} \). \( \langle \text{type} \rangle \texttt{\_map\_break:} \) should also be added to the input stream after the recursion has ended.

An example of recursion with quarks

Quarks are mainly used internally in the expl3 code to define recursion functions such as \texttt{\textbackslash tl\_map\_inline:nn} and so on. Here is a small example to demonstrate how to
use quarks in this fashion. We shall define a command called \texttt{\my_map_dbl:nn} which takes a token list and applies an operation to every pair of tokens. For example, \texttt{\my_map_dbl:nn} \{abcd\} \{[--#1--#2--]-\} would produce “[–a–b–] [–c–d–]’’. Using quarks to define such functions simplifies their logic and ensures robustness in many cases.

Here’s the definition of \texttt{\my_map_dbl:nn}. First of all, define the function that does the processing based on the inline function argument \#2. Then initiate the recursion using an internal function. The token list \#1 is terminated using \texttt{\q_recursion_tail}, with delimiters according to the type of recursion (here a pair of \texttt{\q_recursion_tail}), concluding with \texttt{\q_recursion_stop}. These quarks are used to mark the end of the token list being operated upon.

\begin{verbatim}
\cs_new:Npn \my_map_dbl:nn #1#2
  {
    \cs_set:Npn \__my_map_dbl_fn:nn ##1 ##2 {#2}
    \__my_map_dbl:nn #1 \q_recursion_tail \q_recursion_tail \q_recursion_stop
  }
\end{verbatim}

The definition of the internal recursion function follows. First check if either of the input tokens are the termination quarks. Then, if not, apply the inline function to the two arguments.

\begin{verbatim}
\cs_new:Nn \__my_map_dbl:nn
  {
    \quark_if_recursion_tail_stop:n {#1}
    \quark_if_recursion_tail_stop:n {#2}
    \__my_map_dbl_fn:nn {#1} {#2}
  }
\end{verbatim}

Finally, recurse:

\begin{verbatim}
\__my_map_dbl:nn
\end{verbatim}

Note that contrarily to \LaTeX built-in mapping functions, this mapping function cannot be nested, since the second map would overwrite the definition of \texttt{\__my_map_dbl_fn:nn}.

\section{Scan marks}

Scan marks are control sequences set equal to \texttt{\scan_stop}; hence never expand in an expansion context and are (largely) invisible if they are encountered in a typesetting context.

Like quarks, they can be used as delimiters in weird functions and are often safer to use for this purpose. Since they are harmless when executed by \TeX in non-expandable contexts, they can be used to mark the end of a set of instructions. This allows to skip to that point if the end of the instructions should not be performed (see \texttt{l3regex}).

\begin{verbatim}
\scan_new:N \scan_stop:n \scan_stop:n \scan_stop:n \scan_stop:n \scan_stop:n \scan_stop:n
\end{verbatim}

\texttt{\scan_new:Nn} \texttt{(scan mark)} creates a new \texttt{(scan mark)} which is set equal to \texttt{\scan_stop};. The \texttt{(scan mark)} is defined globally, and an error message is raised if the name was already taken by another scan mark.
\s_stop

Used at the end of a set of instructions, as a marker that can be jumped to using \use_
none_delimit_by_s_stop:w.

\use_none_delimit_by_s_stop:w * \use_none_delimit_by_s_stop:w (tokens) \s_stop

Removes the \textit{tokens} and \s_stop from the input stream. This leads to a low-level \LaTeX
error if \s_stop is absent.
Part VII
The l3tl package

Token lists

\[\text{\LaTeX} \text{ works with tokens, and } \text{\LaTeX}^3 \text{ therefore provides a number of functions to deal with lists of tokens. Token lists may be present directly in the argument to a function:} \]

\[
\texttt{\textbackslash foo:n \{ a collection of \textbackslash tokens \}}
\]
or may be stored in a so-called “token list variable”, which have the suffix tl: a token list variable can also be used as the argument to a function, for example

\[
\texttt{\textbackslash foo:N \_l\_some_tl}
\]

In both cases, functions are available to test and manipulate the lists of tokens, and these have the module prefix tl. In many cases, functions which can be applied to token list variables are paired with similar functions for application to explicit lists of tokens: the two “views” of a token list are therefore collected together here.

A token list (explicit, or stored in a variable) can be seen either as a list of “items”, or a list of “tokens”. An item is whatever \texttt{\textbackslash use:n} would grab as its argument: a single non-space token or a brace group, with optional leading explicit space characters (each item is thus itself a token list). A token is either a normal \texttt{N} argument, or \texttt{\_}, \{, or \} (assuming normal \texttt{\LaTeX} category codes). Thus for example

\[
\{ \text{Hello} \} \text{ \textendash \ world}
\]

contains six items (Hello, w, o, r, l and d), but thirteen tokens (\{, H, e, l, o, \}, \_\_, w, o, r, l and d). Functions which act on items are often faster than their analogue acting directly on tokens.

1 Creating and initialising token list variables

\[
\texttt{\textbackslash tl\_new:N} \texttt{(tl var)}
\]

Creates a new \texttt{(tl var)} or raises an error if the name is already taken. The declaration is global. The \texttt{(tl var)} is initially empty.

\[
\texttt{\textbackslash tl\_const:Nn} \texttt{(tl var) \{\langle token list\rangle\}}
\]

Creates a new constant \texttt{(tl var)} or raises an error if the name is already taken. The value of the \texttt{(tl var)} is set globally to the \texttt{(token list)}.

\[
\texttt{\textbackslash tl\_clear:N (tl var)}
\]

Clears all entries from the \texttt{(tl var)}. 

43
Ensures that the ⟨tl var⟩ exists globally by applying \tl_new:N if necessary, then applies \tl_(g)clear:N to leave the ⟨tl var⟩ empty.

\tl_set_eq:NN ⟨tl var 1⟩ ⟨tl var 2⟩
Sets the content of ⟨tl var 1⟩ equal to that of ⟨tl var 2⟩.

\tl_concat:NNN ⟨tl var 1⟩ ⟨tl var 2⟩ ⟨tl var 3⟩
Concatenates the content of ⟨tl var 2⟩ and ⟨tl var 3⟩ together and saves the result in ⟨tl var 1⟩. The ⟨tl var 2⟩ is placed at the left side of the new token list.

2 Adding data to token list variables

\tl_set:Nn ⟨tl var⟩ ⟨tokens⟩
Sets ⟨tl var⟩ to contain ⟨tokens⟩, removing any previous content from the variable.

\tl_put_left:Nn ⟨tl var⟩ ⟨tokens⟩
Appends ⟨tokens⟩ to the left side of the current content of ⟨tl var⟩.

\tl_put_right:Nn ⟨tl var⟩ ⟨tokens⟩
Appends ⟨tokens⟩ to the right side of the current content of ⟨tl var⟩.
3 Modifying token list variables

\tl_replace_once:Nnn \tl_greplace_once:Nnn

Replaces the first (leftmost) occurrence of \textit{old tokens} in the \textit{tl var} with \textit{new tokens}. \textit{Old tokens} cannot contain \{, \} or # (more precisely, explicit character tokens with category code 1 (begin-group) or 2 (end-group), and tokens with category code 6).

\tl_replace_all:Nnn \tl_greplace_all:Nnn

Replaces all occurrences of \textit{old tokens} in the \textit{tl var} with \textit{new tokens}. \textit{Old tokens} cannot contain \{, \} or # (more precisely, explicit character tokens with category code 1 (begin-group) or 2 (end-group), and tokens with category code 6). As this function operates from left to right, the pattern \textit{old tokens} may remain after the replacement (see \tl_remove_all:Nn for an example).

\tl_remove_once:Nn \tl_gremove_once:Nn

Removes the first (leftmost) occurrence of \textit{tokens} from the \textit{tl var}. \textit{Tokens} cannot contain \{, \} or # (more precisely, explicit character tokens with category code 1 (begin-group) or 2 (end-group), and tokens with category code 6).

\tl_remove_all:Nn \tl_gremove_all:Nn

Removes all occurrences of \textit{tokens} from the \textit{tl var}. \textit{Tokens} cannot contain \{, \} or # (more precisely, explicit character tokens with category code 1 (begin-group) or 2 (end-group), and tokens with category code 6). As this function operates from left to right, the pattern \textit{tokens} may remain after the removal, for instance,

\tl_set:Nn \l_tmpa_tl \{abbccd\} \tl_remove_all:Nn \l_tmpa_tl \{bc\}

results in \l_tmpa_tl containing abcd.

4 Reassigning token list category codes

These functions allow the rescanning of tokens: re-apply \TeX{}’s tokenization process to apply category codes different from those in force when the tokens were absorbed. Whilst this functionality is supported, it is often preferable to find alternative approaches to achieving outcomes rather than rescanning tokens (for example construction of token lists token-by-token with intervening category code changes or using \char_generate:nn).
Sets \(\langle \text{tokens} \rangle\) to contain \(\langle \text{tokens} \rangle\), applying the category code régime specified in the \(\langle \text{setup} \rangle\) before carrying out the assignment. (Category codes applied to tokens not explicitly covered by the \(\langle \text{setup} \rangle\) are those in force at the point of use of \(\texttt{tl_set_rescan:NNn} \).)

This allows the \(\langle \text{tl var} \rangle\) to contain material with category codes other than those that apply when \(\langle \text{tokens} \rangle\) are absorbed. The \(\langle \text{setup} \rangle\) is run within a group and may contain any valid input, although only changes in category codes are relevant. See also \(\texttt{tl_set_rescan:NNn}\).

**\TeXhackers note:** The \(\langle \text{tokens} \rangle\) are first turned into a string (using \texttt{tl_to_str:n}). If the string contains one or more characters with character code \texttt{\textbackslash newlinechar} (set equal to \texttt{\textbackslash endlinechar} unless that is equal to \texttt{32}, before the user \(\langle \text{setup} \rangle\)), then it is split into lines at these characters, then read as if reading multiple lines from a file, ignoring spaces (catcode \texttt{10}) at the beginning and spaces and tabs (character code \texttt{32} or \texttt{9}) at the end of every line. Otherwise, spaces (and tabs) are retained at both ends of the single-line string, as if it appeared in the middle of a line read from a file.

Recans \(\langle \text{tokens} \rangle\) applying the category code régime specified in the \(\langle \text{setup} \rangle\), and leaves the resulting tokens in the input stream. (Category codes applied to tokens not explicitly covered by the \(\langle \text{setup} \rangle\) are those in force at the point of use of \(\texttt{tl_rescan:nn} \).) The \(\langle \text{setup} \rangle\) is run within a group and may contain any valid input, although only changes in category codes are relevant. See also \(\texttt{tl_set_rescan:NNn}\), which is more robust than using \(\texttt{\textbackslash tl_set:NN}\) in the \(\langle \text{tokens} \rangle\) argument of \(\texttt{tl_rescan:nn}\).

**\TeXhackers note:** The \(\langle \text{tokens} \rangle\) are first turned into a string (using \texttt{\textbackslash tl_to_str:n}). If the string contains one or more characters with character code \texttt{\textbackslash newlinechar} (set equal to \texttt{\textbackslash endlinechar} unless that is equal to \texttt{32}, before the user \(\langle \text{setup} \rangle\)), then it is split into lines at these characters, then read as if reading multiple lines from a file, ignoring spaces (catcode \texttt{10}) at the beginning and spaces and tabs (character code \texttt{32} or \texttt{9}) at the end of every line. Otherwise, spaces (and tabs) are retained at both ends of the single-line string, as if it appeared in the middle of a line read from a file.

## 5 Token list conditionals

Tests if the \(\langle \text{token list} \rangle\) consists only of blank spaces (i.e. contains no item). The test is true if \(\langle \text{token list} \rangle\) is zero or more explicit space characters (explicit tokens with character code \texttt{32} and category code \texttt{10}), and is false otherwise.
\tl_if_empty_p:N *
\tl_if_empty_p:c *
\tl_if_empty:NTF *
\tl_if_empty:cTF *
Tests if the \langle token list variable \rangle is entirely empty (i.e. contains no tokens at all).

\tl_if_empty_p:n *
\tl_if_empty_p:(V|o) *
\tl_if_empty:nTF *
\tl_if_empty:(V|o)TF *
Tests if the \langle token list \rangle is entirely empty (i.e. contains no tokens at all).

\tl_if_eq_p:NN *
\tl_if_eq_p:(Nc|cN|cc) *
\tl_if_eq:NN *
\tl_if_eq:(Nc|cN|cc) *
Compares the content of two \langle token list variables \rangle and is logically true if the two contain the same list of tokens (i.e. identical in both the list of characters they contain and the category codes of those characters). Thus for example

\tl_set:Nn \l_tmpa_tl { abc }
\tl_set:Nx \l_tmpb_tl { \tl_to_str:n { abc } }
\tl_if_eq:NNTF \l_tmpa_tl \l_tmpb_tl { true } { false }
yields false.

\tl_if_eq:nnTF *
\tl_if_eq:nn *
\tl_if_eq:nn *
\tl_if_eq:nn *
Tests if \langle token list \rangle \langle token list \rangle contain the same list of tokens, both in respect of character codes and category codes.

\tl_if_in:NnTF *
\tl_if_in:Nn *
\tl_if_in:cn *
\tl_if_in:cn *
Tests if the \langle token list \rangle is found in the content of the \langle tl var \rangle. The \langle token list \rangle cannot contain the tokens \{, \} or \# (more precisely, explicit character tokens with category code 1 (begin-group) or 2 (end-group), and tokens with category code 6).

\tl_if_in:nnTF *
\tl_if_in:nn *
\tl_if_in:nn *
\tl_if_in:nn *
Tests if \langle token lists \rangle is found inside \langle token lists \rangle. The \langle token lists \rangle cannot contain the tokens \{, \} or \# (more precisely, explicit character tokens with category code 1 (begin-group) or 2 (end-group), and tokens with category code 6).

\tl_if_novalue_p:n *
\tl_if_novalue_p:n *
\tl_if_novalue:nTF *
\tl_if_novalue:nTF *
Tests if the \langle token list \rangle is exactly equal to the special \c_novalue_tl marker. This function is intended to allow construction of flexible document interface structures in which missing optional arguments are detected.
Tests if the content of the \textit{tl var} consists of a single item, \textit{i.e.} is a single normal token (neither an explicit space character nor a begin-group character) or a single brace group, surrounded by optional spaces on both sides. In other words, such a token list has token count 1 according to $\texttt{tl_count:N}$.

Updated: 2011-08-13

Tests if the token list has exactly one item, \textit{i.e.} is a single normal token (neither an explicit space character nor a begin-group character) or a single brace group, surrounded by optional spaces on both sides. In other words, such a token list has token count 1 according to $\texttt{tl_count:n}$.

Updated: 2011-08-13

Tests if the token list consists of exactly one token, \textit{i.e.} is either a single space character or a single “normal” token. Token groups (\{...\}) are not single tokens.

New: 2013-07-24

This function compares the \textit{test token list variable} in turn with each of the \textit{token list variable cases}. If the two are equal (as described for $\texttt{tl_if_eq:NNTF}$) then the associated \textit{code} is left in the input stream and other cases are discarded. If any of the cases are matched, the \textit{true code} is also inserted into the input stream (after the code for the appropriate case), while if none match then the \textit{false code} is inserted. The function $\texttt{tl_case:Nn}$, which does nothing if there is no match, is also available.

6 Mapping to token lists

All mappings are done at the current group level, \textit{i.e.} any local assignments made by the \textit{function} or \textit{code} discussed below remain in effect after the loop.

Applies \textit{function} to every \textit{item} in the \textit{tl var}. The \textit{function} receives one argument for each iteration. This may be a number of tokens if the \textit{item} was stored within braces. Hence the \textit{function} should anticipate receiving n-type arguments. See also $\texttt{tl_map_function:nN}$. 

Updated: 2012-06-29
\tl_map_function:nN \{\token list\} \{\function\}

Applies \{\function\} to every \{\item\} in the \{\token list\}. The \{\function\} receives one argument for each iteration. This may be a number of tokens if the \{\item\} was stored within braces. Hence the \{\function\} should anticipate receiving n-type arguments. See also \tl_map_function:NN.

\tl_map_inline:Nn \tl_map_inline:cn

Applies the \{\inline function\} to every \{\item\} stored within the \{\tl var\}. The \{\inline function\} should consist of code which receives the \{\item\} as \#1. See also \tl_map_function:nN.

\tl_map_inline:nn \tl_map_inline:nn

Applies the \{\inline function\} to every \{\item\} stored within the \{\token list\}. The \{\inline function\} should consist of code which receives the \{\item\} as \#1. See also \tl_map_function:nN.

\tl_map_tokens:Nn \tl_map_tokens:cn \tl_map_tokens:nn

Analogue of \tl_map_function:NN which maps several tokens instead of a single function. The \{\code\} receives each item in the \{\tl var\} or \{\tokens\} as two trailing brace groups. For instance,

\tl_map_tokens:Nn \my_tl \{\prg_replicate:nn { 2 } \}

expands to twice each item in the \{\sequence\}: for each item in \my_tl the function \prg_replicate:nn receives 2 and \{\item\} as its two arguments. The function \tl_map_inline:Nn is typically faster but is not expandable.

\tl_map_variable:NNn \tl_map_variable:cNn \tl_map_variable:nNn

Stores each \{\item\} of the \{\tl var\} in turn in the \{\token list\} \{\variable\} and applies the \{\code\}. The \{\code\} will usually make use of the \{\variable\}, but this is not enforced. The assignments to the \{\variable\} are local. Its value after the loop is the last \{\item\} in the \{\tl var\}, or its original value if the \{\tl var\} is blank. See also \tl_map_inline:Nn.

\tl_map_variable:nNn

Stores each \{\item\} of the \{\token list\} in turn in the \{\token list\} \{\variable\} and applies the \{\code\}. The \{\code\} will usually make use of the \{\variable\}, but this is not enforced. The assignments to the \{\variable\} are local. Its value after the loop is the last \{\item\} in the \{\tl var\}, or its original value if the \{\tl var\} is blank. See also \tl_map_inline:nn.
\tl_map_break:  
\tl_map_break:
Used to terminate a \tl_map... function before all entries in the \langle token list variable \rangle have been processed. This normally takes place within a conditional statement, for example
\tl_map_inline:Nn \l_my_tl
{\str_if_eq:nnT { #1 } { bingo } \{ \tl_map_break: \}
% Do something useful
}

See also \tl_map_break:n. Use outside of a \tl_map... scenario leads to low level \TeX errors.

\textbf{\TeXhackers note:} When the mapping is broken, additional tokens may be inserted before the \langle tokens \rangle are inserted into the input stream. This depends on the design of the mapping function.

\tl_map_break:n  
\tl_map_break:n \{(code)\}
Used to terminate a \tl_map... function before all entries in the \langle token list variable \rangle have been processed, inserting the \langle code \rangle after the mapping has ended. This normally takes place within a conditional statement, for example
\tl_map_inline:Nn \l_my_tl
{\str_if_eq:nnT { #1 } { bingo } \{ \tl_map_break:n \{ <code> \} \}
% Do something useful
}

Use outside of a \tl_map... scenario leads to low level \TeX errors.

\textbf{\TeXhackers note:} When the mapping is broken, additional tokens may be inserted before the \langle code \rangle is inserted into the input stream. This depends on the design of the mapping function.
7 Using token lists

\tl_to_str:n \tl_to_str:n \langle token list\rangle

Converts the ⟨token list⟩ to a ⟨string⟩, leaving the resulting character tokens in the input stream. A ⟨string⟩ is a series of tokens with category code 12 (other) with the exception of spaces, which retain category code 10 (space). This function requires only a single expansion. Its argument must be braced.

\textbf{\TeXhackers note:} This is the $\varepsilon$-\TeX primitive $\texttt{\detokenize}$. Converting a ⟨token list⟩ to a ⟨string⟩ yields a concatenation of the string representations of every token in the ⟨token list⟩. The string representation of a control sequence is

- an escape character, whose character code is given by the internal parameter $\texttt{\escapechar}$, absent if the $\texttt{\escapechar}$ is negative or greater than the largest character code;
- the control sequence name, as defined by $\texttt{\cs_to_str:N}$;
- a space, unless the control sequence name is a single character whose category at the time of expansion of $\texttt{\tl_to_str:n}$ is not “letter”.

The string representation of an explicit character token is that character, doubled in the case of (explicit) macro parameter characters (normally #). In particular, the string representation of a token list may depend on the category codes in effect when it is evaluated, and the value of the $\texttt{\escapechar}$: for instance $\texttt{\tl_to_str:n \{a\}}$ normally produces the three character “backslash”, “lower-case a”, “space”, but it may also produce a single “lower-case a” if the escape character is negative and $a$ is currently not a letter.

\tl_to_str:n \tl_to_str:n \tl_to_str:c \tl_to_str:N \tl_to_str:c

Converts the content of the ⟨tl var⟩ into a series of characters with category code 12 (other) with the exception of spaces, which retain category code 10 (space). This ⟨string⟩ is then left in the input stream. For low-level details, see the notes given for $\texttt{\tl_to_str:n}$.

\tl_use:N \tl_use:c

Recovers the content of a ⟨tl var⟩ and places it directly in the input stream. An error is raised if the variable does not exist or if it is invalid. Note that it is possible to use a ⟨tl var⟩ directly without an accessor function.

8 Working with the content of token lists

\tl_count:n \tl_count:n \langle tokens\rangle

Counts the number of ⟨items⟩ in ⟨tokens⟩ and leaves this information in the input stream. Unbraced tokens count as one element as do each token group ⟨{…}⟩. This process ignores any unprotected spaces within ⟨tokens⟩. See also $\texttt{\tl_count:N}$. This function requires three expansions, giving an ⟨integer denotation⟩.
\tl_count:N \tl_var
\tl_count:N \{\tl var\}
Counts the number of token groups in the \langle \tl var \rangle and leaves this information in the input stream. Unbraced tokens count as one element as do each token group \langle \{\ldots\} \rangle. This process ignores any unprotected spaces within the \langle \tl var \rangle. See also \tl_count:n. This function requires three expansions, giving an \langle integer denotation \rangle.

\tl_count_tokens:n
\tl_count_tokens:n \{\langle tokens \rangle\} Counts the number of TEX tokens in the \langle tokens \rangle and leaves this information in the input stream. Every token, including spaces and braces, contributes one to the total; thus for instance, the token count of \texttt{a\{bc\}} is 6.

\tl_reverse:n
\tl_reverse:n \{\langle token list \rangle\} Reverses the order of the \langle items \rangle in the \langle token list \rangle, so that \langle item_1 \rangle \langle item_2 \rangle \langle item_3 \rangle \ldots \langle item_n \rangle becomes \langle item_n \rangle \ldots \langle item_3 \rangle \langle item_2 \rangle \langle item_1 \rangle. This process preserves unprotected space within the \langle token list \rangle. Tokens are not reversed within braced token groups, which keep their outer set of braces. In situations where performance is important, consider \tl_reverse_items:n. See also \tl_reverse:n.

\texttt{TeXhackers} note: The result is returned within \texttt{\unexpanded}, which means that the token list does not expand further when appearing in an \texttt{x}-type argument expansion.

\tl_reverse_items:n
\tl_reverse_items:n \{\langle token list \rangle\} Reverses the order of the \langle items \rangle stored in \langle tl var \rangle, so that \langle item_1 \rangle \langle item_2 \rangle \langle item_3 \rangle \ldots \langle item_n \rangle becomes \langle item_n \rangle \ldots \langle item_3 \rangle \langle item_2 \rangle \langle item_1 \rangle. This process preserves unprotected spaces within the \langle token list variable \rangle. Braced token groups are copied without reversing the order of tokens, but keep the outer set of braces. See also \tl_reverse:n, and, for improved performance, \tl_reverse_items:n.

\texttt{TeXhackers} note: The result is returned within \texttt{\unexpanded}, which means that the token list does not expand further when appearing in an \texttt{x}-type argument expansion.

\tl_trim_spaces:n
\tl_trim_spaces:n \{\langle token list \rangle\} Removes any leading and trailing explicit space characters (explicit tokens with character code 32 and category code 10) from the \langle token list \rangle and leaves the result in the input stream.

\texttt{TeXhackers} note: The result is returned within \texttt{\unexpanded}, which means that the token list does not expand further when appearing in an \texttt{x}-type argument expansion.
\texttt{\textbackslash tl\_trim\_spaces\_apply:nN} \* \texttt{\textbackslash tl\_trim\_spaces\_apply:oN} \* \texttt{\textbackslash tl\_trim\_spaces:N} \texttt{\textbackslash tl\_gtrim\_spaces:N} \texttt{\textbackslash tl\_trim\_spaces:c} \texttt{\textbackslash tl\_gtrim\_spaces:c} \\

\texttt{New: 2017-02-06}

\texttt{\textbackslash tl\_trim\_spaces\_apply:nN} \{\langle token list\rangle\} \{\texttt{function}\}

Removes any leading and trailing explicit space characters (explicit tokens with character code 32 and category code 10) from the $\langle token list\rangle$ and passes the result to the $\langle function\rangle$ as an n-type argument.

\texttt{\textbackslash tl\_trim\_spaces:N} \langle tl var\rangle

Removes any leading and trailing explicit space characters (explicit tokens with character code 32 and category code 10) from the content of the $\langle tl var\rangle$. Note that this therefore resets the content of the variable.

\texttt{\textbackslash tl\_sort:Nn} \langle tl var\rangle \{\langle comparison code\rangle\}

Sorts the items in the $\langle tl var\rangle$ according to the $\langle comparison code\rangle$, and assigns the result to $\langle tl var\rangle$. The details of sorting comparison are described in Section 1.

\texttt{\textbackslash tl\_sort:nN} \* \texttt{\textbackslash tl\_sort:nN} \texttt{\textbackslash tl\_sort:cn} \texttt{\textbackslash tl\_gsort:nN} \texttt{\textbackslash tl\_gsort:cn} \\
\texttt{New: 2017-02-06}

\texttt{\textbackslash tl\_sort:nN} \{\langle token list\rangle\} \{\texttt{conditional}\}

Sorts the items in the $\langle token list\rangle$, using the $\langle conditional\rangle$ to compare items, and leaves the result in the input stream. The $\langle conditional\rangle$ should have signature $:mnTF$, and return \texttt{true} if the two items being compared should be left in the same order, and \texttt{false} if the items should be swapped. The details of sorting comparison are described in Section 1.

\texttt{\textbackslash texhackers\ note}: The result is returned within \texttt{\textbackslash exp\ not:n}, which means that the token list does not expand further when appearing in an \texttt{x}-type or \texttt{e}-type argument expansion.

9 The first token from a token list

Functions which deal with either only the very first item (balanced text or single normal token) in a token list, or the remaining tokens.
Leaves in the input stream the first \langle item \rangle in the \langle token list \rangle, discarding the rest of the \langle token list \rangle. All leading explicit space characters (explicit tokens with character code 32 and category code 10) are discarded; for example

\tl_head:n \{ abc \}

and

\tl_head:n \{ - abc \}

both leave a in the input stream. If the “head” is a brace group, rather than a single token, the braces are removed, and so

\tl_head:n \{ - \{ - ab \} c \}

yields \texttt{ab}. A blank \langle token list \rangle (see \tl_if_blank:nTF) results in \tl_head:n leaving nothing in the input stream.

\textbf{TeXhackers note:} The result is returned within \exp_not:n, which means that the token list does not expand further when appearing in an \texttt{x}-type argument expansion.

Discards all leading explicit space characters (explicit tokens with character code 32 and category code 10) and the first \langle item \rangle in the \langle token list \rangle, and leaves the remaining tokens in the input stream. Thus for example

\tl_tail:n \{ a - \{bc\} d \}

and

\tl_tail:n \{ - a - \{bc\} d \}

both leave \texttt{(bc)d} in the input stream. A blank \langle token list \rangle (see \tl_if_blank:nTF) results in \tl_tail:n leaving nothing in the input stream.

\textbf{TeXhackers note:} The result is returned within \exp_not:n, which means that the token list does not expand further when appearing in an \texttt{x}-type argument expansion.
Tests if the first \langle token \rangle in the \langle token list \rangle has the same category code as the \langle test token \rangle. In the case where the \langle token list \rangle is empty, the test is always false.

Tests if the first \langle token \rangle in the \langle token list \rangle has the same character code as the \langle test token \rangle. In the case where the \langle token list \rangle is empty, the test is always false.

Tests if the first \langle token \rangle in the \langle token list \rangle has the same meaning as the \langle test token \rangle. In the case where \langle token list \rangle is empty, the test is always false.

Tests if the first \langle token \rangle in the \langle token list \rangle is an explicit begin-group character (with category code 1 and any character code), in other words, if the \langle token list \rangle starts with a \c_group_begin_token. In particular, the test is false if the \langle token list \rangle starts with an implicit token such as \c_space_token, or if it is empty. This function is useful to implement actions on token lists on a token by token basis.

Tests if the first \langle token \rangle in the \langle token list \rangle is a normal N-type argument. In other words, it is neither an explicit space character (explicit token with character code 32 and category code 10) nor an explicit begin-group character (with category code 1 and any character code). An empty argument yields false, as it does not have a “normal” first token. This function is useful to implement actions on token lists on a token by token basis.
10 Using a single item

\tl_item:nn \{token list\} \{integer expression\}

Indexing items in the \textit{token list} from 1 on the left, this function evaluates the \textit{integer expression} and leaves the appropriate item from the \textit{token list} in the input stream. If the \textit{integer expression} is negative, indexing occurs from the right of the token list, starting at $-1$ for the right-most item. If the index is out of bounds, then the function expands to nothing.

\textbf{\TeX}hackers note: The result is returned within the \texttt{\unexpanded} primitive (\texttt{\exp_not:n}), which means that the \textit{item} does not expand further when appearing in an \texttt{x}-type argument expansion.

\tl_rand_item:N \{tl \ var\}
\tl_rand_item:n \{\{token list\}\}

Selects a pseudo-random item of the \textit{token list}. If the \textit{token list} is blank, the result is empty. This is not available in older versions of \TeX.

\textbf{\TeX}hackers note: The result is returned within the \texttt{\unexpanded} primitive (\texttt{\exp_not:n}), which means that the \textit{item} does not expand further when appearing in an \texttt{x}-type argument expansion.
\tl_range:NNn \tl_range:nnn

Leaves in the input stream the items from the (start index) to the (end index) inclusive. Spaces and braces are preserved between the items returned (but never at either end of the list). Here (start index) and (end index) should be (integer expressions). For describing in detail the functions’ behavior, let m and n be the start and end index respectively. If either is 0, the result is empty. A positive index means ‘start counting from the left end’, and a negative index means ‘from the right end’. Let l be the count of the token list.

The actual start point is determined as M = m if m > 0 and as M = l + m + 1 if m < 0. Similarly the actual end point is N = n if n > 0 and N = l + n + 1 if n < 0. If M > N, the result is empty. Otherwise it consists of all items from position M to position N inclusive; for the purpose of this rule, we can imagine that the token list extends at infinity on either side, with void items at positions s for s ≤ 0 or s > l.

Spaces in between items in the actual range are preserved. Spaces at either end of the token list will be removed anyway (think to the token list being passed to \tl_trim_spaces:n to begin with.

Thus, with l = 7 as in the examples below, all of the following are equivalent and result in the whole token list

\tl_range:nnn { abcd-{e{}}fg } { 1 } { 7 }
\tl_range:nnn { abcd-{e{}}fg } { 1 } { 12 }
\tl_range:nnn { abcd-{e{}}fg } { -7 } { 7 }
\tl_range:nnn { abcd-{e{}}fg } { -12 } { 7 }

Here are some more interesting examples. The calls

\io_term:x { \tl_range:nnn { abcd-{e{}}fg } { 2 } { 5 } }
\io_term:x { \tl_range:nnn { abcd-{e{}}fg } { 2 } { -3 } }
\io_term:x { \tl_range:nnn { abcd-{e{}}fg } { -6 } { 5 } }
\io_term:x { \tl_range:nnn { abcd-{e{}}fg } { -6 } { -3 } }

are all equivalent and will print bcd{e{}} on the terminal; similarly

\io_term:x { \tl_range:nnn { abcd-{e{}}fg } { 2 } { 5 } }
\io_term:x { \tl_range:nnn { abcd-{e{}}fg } { 2 } { -3 } }
\io_term:x { \tl_range:nnn { abcd-{e{}}fg } { -6 } { 5 } }
\io_term:x { \tl_range:nnn { abcd-{e{}}fg } { -6 } { -3 } }

are all equivalent and will print bcd \{e{}} on the terminal (note the space in the middle).

To the contrary,

\tl_range:nnn { abcd-{e{}}f } { 2 } { 4 }

will discard the space after ‘d’.

If we want to get the items from, say, the third to the last in a token list <tl>, the call is \tl_range:nnn { <tl> } { 3 } { -1 }. Similarly, for discarding the last item, we can do \tl_range:nnn { <tl> } { 1 } { -2 }.

For better performance, see \tl_range_braced:nnn and \tl_range_unbraced:nnn.

\TeXhackers note: The result is returned within the \unexpanded primitive (\exp_not:n), which means that the ⟨item⟩ does not expand further when appearing in an x-type argument expansion.
11 Viewing token lists

\tl_show:N
\tl_show:c
Updated: 2015-08-01

Displays the content of the ⟨tl var⟩ on the terminal.

**TeXhacker note:** This is similar to the \TeX primitive \show, wrapped to a fixed number of characters per line.

Write the ⟨token list⟩ in the log file. See also \tl_show:n which displays the result in the terminal.

12 Constant token lists

\c_empty_tl
Constant that is always empty.

\c_novalue_tl
A marker for the absence of an argument. This constant \tl can safely be typeset \(\text{cf. } \\texttt{\textbackslash q\_}\text{-nil}\)\), with the result being \texttt{-NoValue-}. It is important to note that \c_novalue_tl is constructed such that it will not match the simple text input \texttt{-NoValue-}, \textit{i.e.} that

\tl_if_eq:VnTF \c_novalue_tl { -NoValue- }

is logically \texttt{false}. The \c_novalue_tl marker is intended for use in creating document-level interfaces, where it serves as an indicator that an (optional) argument was omitted. In particular, it is distinct from a simple empty \tl.

\c_space_tl
An explicit space character contained in a token list \(\text{compare this with } \c_space_token\). For use where an explicit space is required.
13 Scratch token lists

\l_tmpa_tl \l_tmpb_tl

Scratch token lists for local assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

\g_tmpa_tl \g_tmpb_tl

Scratch token lists for global assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.
Part VIII

The \texttt{l3str} package: Strings

\TeX{} associates each character with a category code: as such, there is no concept of a “string” as commonly understood in many other programming languages. However, there are places where we wish to manipulate token lists while in some sense “ignoring” category codes: this is done by treating token lists as strings in a \TeX{} sense.

A \TeX{} string (and thus an \texttt{expl3} string) is a series of characters which have category code 12 (“other”) with the exception of space characters which have category code 10 (“space”). Thus at a technical level, a \TeX{} string is a token list with the appropriate category codes. In this documentation, these are simply referred to as strings.

String variables are simply specialised token lists, but by convention should be named with the suffix \ldots\texttt{str}. Such variables should contain characters with category code 12 (other), except spaces, which have category code 10 (blank space). All the functions in this module which accept a token list argument first convert it to a string using \texttt{\tl_to_-str:n} for internal processing, and do not treat a token list or the corresponding string representation differently.

As a string is a subset of the more general token list, it is sometimes unclear when one should be used over the other. Use a string variable for data that isn’t primarily intended for typesetting and for which a level of protection from unwanted expansion is suitable. This data type simplifies comparison of variables since there are no concerns about expansion of their contents.

The functions \texttt{cs_to_str:N}, \texttt{\tl_to_str:n}, \texttt{\tl_to_str:N} and \texttt{\token_to_str:N} (and variants) generate strings from the appropriate input: these are documented in \texttt{l3basics}, \texttt{l3tl} and \texttt{l3token}, respectively.

Most expandable functions in this module come in three flavours:

\begin{itemize}
\item \texttt{\str_\ldots:N}, which expect a token list or string variable as their argument;
\item \texttt{\str_\ldots:n}, taking any token list (or string) as an argument;
\item \texttt{\str_\ldots_ignore_spaces:n}, which ignores any space encountered during the operation: these functions are typically faster than those which take care of escaping spaces appropriately.
\end{itemize}

\section{Building strings}

\begin{itemize}
\item \texttt{\str_new:N} \langle \texttt{str var} \rangle
\end{itemize}

Creates a new \langle \texttt{str var} \rangle or raises an error if the name is already taken. The declaration is global. The \langle \texttt{str var} \rangle is initially empty.

\begin{itemize}
\item \texttt{\str_const:Nn} \langle \texttt{str var} \rangle \{\langle \texttt{token list} \rangle\}
\end{itemize}

Creates a new constant \langle \texttt{str var} \rangle or raises an error if the name is already taken. The value of the \langle \texttt{str var} \rangle is set globally to the \langle \texttt{token list} \rangle, converted to a string.
\str_clear:N \str_clear:c \str_gclear:N \str_gclear:c

Clears the content of the \langle str var \rangle.

\str_clear_new:N \str_clear_new:c

Ensures that the \langle str var \rangle exists globally by applying \str_new:N if necessary, then applies \str_(g)clear:N to leave the \langle str var \rangle empty.

\str_set_eq:NN \str_set_eq: (cN | Nx | cn | cV | cx) \str_gset_eq:NN \str_gset_eq: (cN | Nx | cn | cV | cx)

Sets the content of \langle str var_1 \rangle equal to that of \langle str var_2 \rangle.

\str_concat:NNN \str_concat:ccc \str_gconcat:NNN \str_gconcat:ccc

Concatenates the content of \langle str var_2 \rangle and \langle str var_3 \rangle together and saves the result in \langle str var_1 \rangle. The \langle str var_2 \rangle is placed at the left side of the new string variable. The \langle str var_2 \rangle and \langle str var_3 \rangle must indeed be strings, as this function does not convert their contents to a string.

2 Adding data to string variables

\str_set:Nn \str_set: (cV | cx) \str_gset:Nn \str_gset: (cV | cx)

Converts the \langle token list \rangle to a \langle string \rangle, and stores the result in \langle str var \rangle.

\str_put_left:Nn \str_put_left: (cV | cx) \str_gput_left:Nn \str_gput_left: (cV | cx)

Converts the \langle token list \rangle to a \langle string \rangle, and prepends the result to \langle str var \rangle. The current contents of the \langle str var \rangle are not automatically converted to a string.
Converts the \{token list\} to a \{string\}, and appends the result to \{str var\}. The current contents of the \{str var\} are not automatically converted to a string.

## 3 Modifying string variables

\str_replace_once:Nnn \{str var\} \{old\} \{new\}

Converts the \{old\} and \{new\} token lists to strings, then replaces the first (leftmost) occurrence of \{old string\} in the \{str var\} with \{new string\}.

\str_replace_all:Nnn \{str var\} \{old\} \{new\}

Converts the \{old\} and \{new\} token lists to strings, then replaces all occurrences of \{old string\} in the \{str var\} with \{new string\}. As this function operates from left to right, the pattern \{old string\} may remain after the replacement (see \str_remove_all:Nn for an example).

\str_remove_once:Nn \{str var\} \{token list\}

Converts the \{token list\} to a \{string\} then removes the first (leftmost) occurrence of \{string\} from the \{str var\}.

\str_remove_all:Nn \{str var\} \{token list\}

Converts the \{token list\} to a \{string\} then removes all occurrences of \{string\} from the \{str var\}. As this function operates from left to right, the pattern \{string\} may remain after the removal, for instance,

```
\str_set:Nn \l_tmpa_str {abbccd} \str_remove_all:Nn \l_tmpa_str {bc}
```

results in \l_tmpa_str containing abcd.
4 String conditionals

\str_if_exist_p:N \str_if_exist_p:C \str_if_exist:NTF \str_if_exist:cTF

Tests whether the \langle str var \rangle is currently defined. This does not check that the \langle str var \rangle really is a string.

\str_if_empty_p:N \str_if_empty_p:C \str_if_empty:NTF \str_if_empty:cTF

Tests if the \langle string variable \rangle is entirely empty (i.e. contains no characters at all).

\str_if_eq_p:NN \str_if_eq_p:(Nc|cN|cc) \str_if_eq:NN \str_if_eq:(Vn|on|no|nV|VV|vn|nv|ee)

Compares the content of two \langle str variables \rangle and is logically true if the two contain the same characters in the same order.

\str_if_eq_p:nn \str_if_eq_p:(Vn|on|no|nV|VV|vn|nv|ee) \str_if_eq:nn

Compares the two \langle token lists \rangle on a character by character basis (namely after converting them to strings), and is true if the two \langle strings \rangle contain the same characters in the same order. Thus for example

\str_if_eq_p:no \{ abc \} \{ \tl_to_str:n \{ abc \} \}

is logically true.

\str_if_in:NnTF \str_if_in:cnTF \str_if_in:nnTF

Converts the \langle token list \rangle to a \langle string \rangle and tests if that \langle string \rangle is found in the content of the \langle str var \rangle.

\str_if_in:nnTF

Converts both \langle token lists \rangle to \langle strings \rangle and tests whether \langle string2 \rangle is found inside \langle string1 \rangle.
\str_case:nn \str_case:(Vn|on|nV|nv) \str_case:nnTF \str_case:(Vn|on|nV|nv)TF

\str_case_e:nn \str_case_e:nnTF

\str_map_function:NN \str_map_function:CN \str_map_function:nN

5 Mapping to strings

All mappings are done at the current group level, i.e. any local assignments made by the \langle function\rangle or \langle code\rangle discussed below remain in effect after the loop.

\str_map_function:NN (str var) \langle function\rangle

Applies \langle function\rangle to every \langle character\rangle in the \langle str var\rangle including spaces. See also \str_map_function:CN.

\str_map_function:nN \langle token list\rangle \langle function\rangle

Converts the \langle token list\rangle to a \langle string\rangle then applies \langle function\rangle to every \langle character\rangle in the \langle string\rangle including spaces. See also \str_map_function:NN.
\texttt{\textbackslash \str_map_inline:Nn} \texttt{\textbackslash \str_map_inline:cn} \texttt{\textbackslash \str_map_inline:nn} \texttt{\textbackslash \str_map_variable:NNn} \texttt{\textbackslash \str_map_variable:cNn} \texttt{\textbackslash \str_map_variable:nNn} \texttt{\textbackslash \str_map_break:} \texttt{\textbackslash \str_map_break:n}

\texttt{\str_map_inline:Nn} \texttt{(str \ var)} \texttt{\{(inline \ function\)}}

Applies the \texttt{(inline \ function)} to every \texttt{(character)} in the \texttt{(str \ var)} including spaces. The \texttt{(inline \ function)} should consist of code which receives the \texttt{(character)} as \#1. See also \texttt{\str_map_function:NN}.

\texttt{\str_map_inline:nn}\texttt{\{(token \ list\)}} \texttt{\{(inline \ function\)}}

Converts the \texttt{(token \ list)} to a \texttt{(string)} then applies the \texttt{(inline \ function)} to every \texttt{(character)} in the \texttt{(string)} including spaces. The \texttt{(inline \ function)} should consist of code which receives the \texttt{(character)} as \#1. See also \texttt{\str_map_function:NN}.

\texttt{\str_map_variable:NNn} \texttt{\str_map_variable:cNn} \texttt{\str_map_variable:nNn}

\texttt{\str_map_variable:NNn} \texttt{(str \ var)} \texttt{\{(variable\)}} \texttt{\{(code\)}}

Stores each \texttt{(character)} of the \texttt{(string)} (including spaces) in turn in the \texttt{(string or token list)} \texttt{(variable)} and applies the \texttt{(code)}. The \texttt{(code)} will usually make use of the \texttt{(variable)}, but this is not enforced. The assignments to the \texttt{(variable)} are local. Its value after the loop is the last \texttt{(character)} in the \texttt{(string)}, or its original value if the \texttt{(string)} is empty. See also \texttt{\str_map_inline:Nn}.

\texttt{\str_map_variable:nNn}

\texttt{\str_map_variable:nNn} \texttt{(token \ list)} \texttt{\{(variable\)}} \texttt{\{(code\)}}

Converts the \texttt{(token \ list)} to a \texttt{(string)} then stores each \texttt{(character)} in the \texttt{(string)} (including spaces) in turn in the \texttt{(string or token list)} \texttt{(variable)} and applies the \texttt{(code)}. The \texttt{(code)} will usually make use of the \texttt{(variable)}, but this is not enforced. The assignments to the \texttt{(variable)} are local. Its value after the loop is the last \texttt{(character)} in the \texttt{(string)}, or its original value if the \texttt{(string)} is empty. See also \texttt{\str_map_inline:Nn}.

\texttt{\str_map_break:} \texttt{\textbackslash \str_map_break:}

Used to terminate a \texttt{\str_map...} function before all characters in the \texttt{(string)} have been processed. This normally takes place within a conditional statement, for example

\begin{verbatim}
\str_map_inline:Nn \l_my_str
{  \str_if_eq:nnT { #1 } { bingo } { \str_map_break: }
  \% Do something useful
}
\end{verbatim}

See also \texttt{\str_map_break:n}. Use outside of a \texttt{\str_map...} scenario leads to low level \TeX\ errors.

\textbf{\TeX\hackers \texttt{name}:} When the mapping is broken, additional tokens may be inserted before continuing with the code that follows the loop. This depends on the design of the mapping function.
\str_map_break:n \str_map_break:n {<code>}

Used to terminate a \str_map... function before all characters in the \langle string\rangle have been processed, inserting the \langle code\rangle after the mapping has ended. This normally takes place within a conditional statement, for example

\str_map_inline:Nn \l_my_str
\{\str_if_eq:nnT { #1 } { bingo }\}
\{ \str_map_break:n {<code>} \}
\% Do something useful

Use outside of a \str_map... scenario leads to low level \TeX{} errors.

\TeX{}hackers note: When the mapping is broken, additional tokens may be inserted before the \langle code\rangle is inserted into the input stream. This depends on the design of the mapping function.

6 Working with the content of strings

\str_use:N \str_use:N \langle str var\rangle

Recovers the content of a \langle str var\rangle and places it directly in the input stream. An error is raised if the variable does not exist or if it is invalid. Note that it is possible to use a \langle str\rangle directly without an accessor function.

\str_count:n \str_count:n \langle token list\rangle
\str_count:N \str_count:N \langle token list\rangle
\str_count:c \str_count:c \langle token list\rangle
\str_count:n \str_count:n \langle token list\rangle
\str_count:n \str_count:n \langle token list\rangle
\str_count:n \str_count:n \langle token list\rangle
\str_count:n \str_count:n \langle token list\rangle
\str_count:n \str_count:n \langle token list\rangle
\str_count:n \str_count:n \langle token list\rangle

Leaves in the input stream the number of characters in the string representation of \langle token list\rangle, as an integer denotation. The functions differ in their treatment of spaces. In the case of \str_count:N and \str_count:n, all characters including spaces are counted. The \str_count:ignore_spaces:n function leaves the number of non-space characters in the input stream.

\str_count_spaces:n \str_count_spaces:n \langle token list\rangle
\str_count_spaces:C \str_count_spaces:C \langle token list\rangle
\str_count_spaces:n \str_count_spaces:n \langle token list\rangle
\str_count_spaces:n \str_count_spaces:n \langle token list\rangle
\str_count_spaces:n \str_count_spaces:n \langle token list\rangle
\str_count_spaces:n \str_count_spaces:n \langle token list\rangle

Leaves in the input stream the number of space characters in the string representation of \langle token list\rangle, as an integer denotation. Of course, this function has no _ignore_spaces variant.
Converts the \textit{token list} into a \textit{string}. The first character in the \textit{string} is then left in the input stream, with category code “other”. The functions differ if the first character is a space: \texttt{str\_head:N} and \texttt{str\_head:n} return a space token with category code 10 (blank space), while the \texttt{str\_head\_ignore\_spaces:n} function ignores this space character and leaves the first non-space character in the input stream. If the \textit{string} is empty (or only contains spaces in the case of the \_ignore\_spaces function), then nothing is left on the input stream.

Converts the \textit{token list} to a \textit{string}, removes the first character, and leaves the remaining characters (if any) in the input stream, with category codes 12 and 10 (for spaces). The functions differ in the case where the first character is a space: \texttt{str\_tail:N} and \texttt{str\_tail:n} only trim that space, while \texttt{str\_tail\_ignore\_spaces:n} removes the first non-space character and any space before it. If the \textit{token list} is empty (or blank in the case of the \_ignore\_spaces variant), then nothing is left on the input stream.

Converts the \textit{token list} to a \textit{string}, and leaves in the input stream the character in position \textit{integer expression} of the \textit{string}, starting at 1 for the first (left-most) character. In the case of \texttt{str\_item:Nn} and \texttt{str\_item:nn}, all characters including spaces are taken into account. The \texttt{str\_item\_ignore\_spaces:nn} function skips spaces when counting characters. If the \textit{integer expression} is negative, characters are counted from the end of the \textit{string}. Hence, $-1$ is the right-most character, \textit{etc}. 

67
Converts the \textit{(token list)} to a \textit{(string)}, and leaves in the input stream the characters from the \textit{(start index)} to the \textit{(end index)} inclusive. Spaces are preserved and counted as items (contrast this with \texttt{\textbackslash tl\_range:nnn} where spaces are not counted as items and are possibly discarded from the output).

Here \textit{(start index)} and \textit{(end index)} should be integer denotations. For describing in detail the functions’ behavior, let \( m \) and \( n \) be the start and end index respectively. If either is 0, the result is empty. A positive index means ‘start counting from the left end’, a negative index means ‘start counting from the right end’. Let \( l \) be the count of the token list.

The actual start point is determined as \( M = m \) if \( m > 0 \) and as \( M = l + m + 1 \) if \( m < 0 \). Similarly the actual end point is \( N = n \) if \( n > 0 \) and \( N = l + n + 1 \) if \( n < 0 \). If \( M > N \), the result is empty. Otherwise it consists of all items from position \( M \) to position \( N \) inclusive; for the purpose of this rule, we can imagine that the token list extends at infinity on either side, with void items at positions \( s \) for \( s \leq 0 \) or \( s > l \). For instance,

\begin{verbatim}
 \io\texttt{word}:x { \texttt{\textbackslash str\_range:nnn} { abcdef } { 2 } { 5 } }
 \io\texttt{word}:x { \texttt{\textbackslash str\_range:nnn} { abcdef } { -4 } { -1 } }
 \io\texttt{word}:x { \texttt{\textbackslash str\_range:nnn} { abcdef } { -2 } { -1 } }
 \io\texttt{word}:x { \texttt{\textbackslash str\_range:nnn} { abcdef } { 0 } { -1 } }
\end{verbatim}

prints \texttt{bcde}, \texttt{cdef}, \texttt{ef}, and an empty line to the terminal. The \textit{(start index)} must always be smaller than or equal to the \textit{(end index)}: if this is not the case then no output is generated. Thus

\begin{verbatim}
 \io\texttt{word}:x { \texttt{\textbackslash str\_range:nnn} { abcdef } { 5 } { 2 } }
 \io\texttt{word}:x { \texttt{\textbackslash str\_range:nnn} { abcdef } { -1 } { -4 } }
\end{verbatim}

both yield empty strings.

The behavior of \texttt{\textbackslash str\_range\_ignore\_spaces:nnn} is similar, but spaces are removed before starting the job. The input

\begin{verbatim}
 \io\texttt{word}:x { \texttt{\textbackslash str\_range:nnn} { abcdefg } { 2 } { 5 } }
 \io\texttt{word}:x { \texttt{\textbackslash str\_range:nnn} { abcdefg } { 2 } { -3 } }
 \io\texttt{word}:x { \texttt{\textbackslash str\_range:nnn} { abcdefg } { -6 } { 5 } }
 \io\texttt{word}:x { \texttt{\textbackslash str\_range:nnn} { abcdefg } { -6 } { -3 } }
 \io\texttt{word}:x { \texttt{\textbackslash str\_range:nnn} { abc-efg } { 2 } { 5 } }
 \io\texttt{word}:x { \texttt{\textbackslash str\_range:nnn} { abc-efg } { 2 } { -3 } }
 \io\texttt{word}:x { \texttt{\textbackslash str\_range:nnn} { abc-efg } { -6 } { 5 } }
 \io\texttt{word}:x { \texttt{\textbackslash str\_range:nnn} { abc-efg } { -6 } { -3 } }
 \io\texttt{word}:x { \texttt{\textbackslash str\_range\_ignore\_spaces:nnn} { abcdefg } { 2 } { 5 } }
 \io\texttt{word}:x { \texttt{\textbackslash str\_range\_ignore\_spaces:nnn} { abcdefg } { 2 } { -3 } }
 \io\texttt{word}:x { \texttt{\textbackslash str\_range\_ignore\_spaces:nnn} { abcdefg } { -6 } { 5 } }
 \io\texttt{word}:x { \texttt{\textbackslash str\_range\_ignore\_spaces:nnn} { abcdefg } { -6 } { -3 } }
\end{verbatim}

68
will print four instances of \texttt{bcde}, four instances of \texttt{bc e} and eight instances of \texttt{bcde}.

7 String manipulation

\input{sections/7-string-manipulation}

\begin{itemize}
\item Caseless comparisons: use \texttt{\str_foldcase:n} for this situation (case folding is distinct from lower casing).
\item Case changing text for typesetting: see the \texttt{\text_lowercase:n(n)}, \texttt{\text_uppercase:n(n)} and \texttt{\text_titlecase:n(n)} functions which correctly deal with context-dependence and other factors appropriate to text case changing.
\end{itemize}

\TeX{}hackers note: As with all expl3 functions, the input supported by \texttt{\str_foldcase:n} is \textit{engine-native} characters which are or interoperate with UTF-8. As such, when used with pdf\TeX{} only the Latin alphabet characters A–Z are case-folded \textit{(i.e. the ASCII range which coincides with UTF-8)}. Full UTF-8 support is available with both Xpdf\TeX{} and Lua\TeX{.}
\texttt{\textbackslash str\_foldcase:n \{\textlangle tokens\textrangle\}}

Converts the input (\textit{tokens}) to their string representation, as described for \texttt{\textbackslash tl\_to\_str:n}, and then folds the case of the resulting (\textit{string}) to remove case information. The result of this process is left in the input stream.

String folding is a process used for material such as identifiers rather than for “text”. The folding provided by \texttt{\textbackslash str\_foldcase:n} follows the mappings provided by the Unicode Consortium, who state:

Case folding is primarily used for caseless comparison of text, such as identifiers in a computer program, rather than actual text transformation. Case folding in Unicode is based on the lowercase mapping, but includes additional changes to the source text to help make it language-insensitive and consistent. As a result, case-folded text should be used solely for internal processing and generally should not be stored or displayed to the end user.

The folding approach implemented by \texttt{\textbackslash str\_foldcase:n} follows the “full” scheme defined by the Unicode Consortium (\textit{e.g.} SSfolds to SS). As case-folding is a language-insensitive process, there is no special treatment of Turkic input (\textit{i.e.} \texttt{i} always folds to \texttt{i} and not to \texttt{ı}).

\textbf{\TeX}hackers note: As with all expl3 functions, the input supported by \texttt{\textbackslash str\_foldcase:n} is engine-native characters which are or interoperate with UTF-8. As such, when used with pdf\TeX only the Latin alphabet characters A–Z are case-folded (\textit{i.e.} the ASCII range which coincides with UTF-8). Full UTF-8 support is available with both Xe\TeX and Lua\TeX, subject only to the fact that Xe\TeX in particular has issues with characters of code above hexadecimal 0xFFFF when interacting with \texttt{\textbackslash tl\_to\_str:n}.

\section{Viewing strings}

\texttt{\textbackslash str\_show:N \{\textlangle str var\textrangle\}}

Displays the content of the \textit{\{str var\}} on the terminal.

\texttt{\textbackslash str\_log:N \{\textlangle str var\textrangle\}}

Writes the content of the \textit{\{str var\}} in the log file.
9  Constant token lists

\c_\texttt{\_ampersand\_str} \c_\texttt{\_atsign\_str} \c_\texttt{\_backslash\_str} \c_\texttt{\_left\_brace\_str} \c_\texttt{\_right\_brace\_str} \c_\texttt{\_circumflex\_str} \c_\texttt{\_colon\_str} \c_\texttt{\_dollar\_str} \c_\texttt{\_hash\_str} \c_\texttt{\_percent\_str} \c_\texttt{\_tilde\_str} \c_\texttt{\_underscore\_str}

New: 2015-09-19

Constant strings, containing a single character token, with category code 12.

10  Scratch strings

\l_\texttt{\_tmpa\_str} \l_\texttt{\_tmpb\_str}

Scratch strings for local assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

\g_\texttt{\_tmpa\_str} \g_\texttt{\_tmpb\_str}

Scratch strings for global assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.
Part IX
The l3str-convert package: string encoding conversions

1 Encoding and escaping schemes

Traditionally, string encodings only specify how strings of characters should be stored as bytes. However, the resulting lists of bytes are often to be used in contexts where only a restricted subset of bytes are permitted (e.g., PDF string objects, URLs). Hence, storing a string of characters is done in two steps.

- The code points (“character codes”) are expressed as bytes following a given “encoding”. This can be utf-16, ISO 8859-1, etc. See Table 1 for a list of supported encodings.
- Bytes are translated to TeX tokens through a given “escaping”. Those are defined for the most part by the pdf file format. See Table 2 for a list of escaping methods supported.

2 Conversion functions

\str_set_convert:Nnnn \str_gset_convert:Nnnn

This function converts the \langle string \rangle from the encoding given by \langle name 1 \rangle to the encoding given by \langle name 2 \rangle, and stores the result in the \langle str var \rangle. Each \langle name \rangle can have the form \langle encoding \rangle or \langle encoding ⟩/\langle escaping \rangle, where the possible values of \langle encoding \rangle and \langle escaping \rangle are given in Tables 1 and 2, respectively. The default escaping is to input and output bytes directly. The special case of an empty \langle name \rangle indicates the use of "native" strings, 8-bit for pdfTEX, and Unicode strings for the other two engines.

For example,

\str_set_convert:Nnnn \l_foo_str \{ Hello! \} \{ \} \text{ utf16/hex }

results in the variable \l_foo_str holding the string \text{FEFF00480065006C0066006F0021}. This is obtained by converting each character in the (native) string \text{Hello!} to the utf-16 encoding, and expressing each byte as a pair of hexadecimal digits. Note the presence of a (big-endian) byte order mark *FEFF, which can be avoided by specifying the encoding utf16be/hex.

An error is raised if the \langle string \rangle is not valid according to the \langle escaping 1 \rangle and \langle encoding 1 \rangle, or if it cannot be reencoded in the \langle encoding 2 \rangle and \langle escaping 2 \rangle (for instance, if a character does not exist in the \langle encoding 2 \rangle). Erroneous input is replaced by the Unicode replacement character *FFFD, and characters which cannot be reencoded are replaced by either the replacement character *FFFD if it exists in the \langle encoding 2 \rangle, or an encoding-specific replacement character, or the question mark character.

\text{5Encodings and escapings will be added as they are requested.}
Table 1: Supported encodings. Non-alphanumeric characters are ignored, and capital letters are lower-cased before searching for the encoding in this list.

As \texttt{\str_set_convert:NnnnTF}, converts the \texttt{\langle string\rangle} from the encoding given by \texttt{\langle name 1\rangle} to the encoding given by \texttt{\langle name 2\rangle}, and assigns the result to \texttt{\langle str var\rangle}. Contrarily to \texttt{\str_set_convert:Nnnn}, the conditional variant does not raise errors in case the \texttt{\langle string\rangle} is not valid according to the \texttt{\langle name 1\rangle} encoding, or cannot be expressed in the \texttt{\langle name 2\rangle} encoding. Instead, the \texttt{\langle false code\rangle} is performed.

### 3 Creating 8-bit mappings

\texttt{\str_declare_eight_bit_encoding:nnn} declares the encoding \texttt{\langle name\rangle} to map bytes to Unicode characters according to the \texttt{\langle mapping\rangle}, and map those bytes which are not mentioned in the \texttt{\langle mapping\rangle} either to the replacement character (if they appear in \texttt{\langle missing\rangle}), or to themselves.

### 4 Possibilities, and things to do

Encoding/escaping-related tasks.

- In Xe\TeX/Lua\TeX, would it be better to use the `\ldots` approach to build a string from a given list of character codes? Namely, within a group, assign 0-9a-f and all characters we want to category “other”, then assign `\^` the category superscript, and use `\scantokens`.
- Change \texttt{\str_set_convert:Nnnn} to expand its last two arguments.
- Describe the internal format in the code comments. Refuse code points in `[D800,DFFF]` in the internal representation?
- Add documentation about each encoding and escaping method, and add examples.
- The \texttt{\hex} unescaping should raise an error for odd-token count strings.
- Decide what bytes should be escaped in the \texttt{\url} escaping. Perhaps the characters `!\(\*$%^&/-\0123456789_` are safe, and all other characters should be escaped?
- Automate generation of 8-bit mapping files.
- Change the framework for 8-bit encodings: for decoding from 8-bit to Unicode, use 256 integer registers; for encoding, use a tree-box.
- More encodings (see Heiko’s \texttt{stringenc}). CESU?
- More escapings: \texttt{\ascii85}, shell escapes, lua escapes, etc.?
Part X
The l3seq package
Sequences and stacks

\LaTeX3 implements a “sequence” data type, which contain an ordered list of entries which may contain any (balanced text). It is possible to map functions to sequences such that the function is applied to every item in the sequence.

Sequences are also used to implement stack functions in \LaTeX3. This is achieved using a number of dedicated stack functions.

1 Creating and initialising sequences

\seq_new:N \seq_new:c

\seq_new:N \seq_new:c \hfill \text{Creates a new (sequence) or raises an error if the name is already taken. The declaration is global. The (sequence) initially contains no items.}

\seq_clear:N \seq_clear:c \hfill \text{Clears all items from the (sequence).}

\seq_gclear:N \seq_gclear:c \hfill \text{Ensures that the (sequence) exists globally by applying } \seq_new:N \text{if necessary, then applies } \seq_(g)\text{clear:N to leave the (sequence) empty.}

\seq_set_eq:NN \seq_set_eq:cn \seq_gset_eq:NN \seq_gset_eq:cn \hfill \text{Sets the content of (sequence1) equal to that of (sequence2).}

\seq_set_from_clist:NN \seq_set_from_clist:cn \seq_set_from_clist:(cN|Nc) \seq_set_from_clist:cn \hfill \text{Converts the data in the (comma list) into a (sequence): the original (comma list) is unchanged.}

\text{Rev: 2014–07–17}
\seq_const_from_clist:Nn \seq_const_from_clist:cn

New: 2017-11-28

Create a new constant \langle seq var \rangle or raises an error if the name is already taken. The \langle seq var \rangle is set globally to contain the items in the \langle comma list \rangle.

\seq_set_split:Nnn \seq_set_split:NnV \seq_gset_split:Nnn \seq_gset_split:NnV

New: 2011-08-15
Updated: 2012-07-02

Splits the \langle token list \rangle into \langle items \rangle separated by \langle delimiter \rangle, and assigns the result to the \langle sequence \rangle. Spaces on both sides of each \langle item \rangle are ignored, then one set of outer braces is removed (if any); this space trimming behaviour is identical to that of \texttt{l3clist} functions. Empty \langle items \rangle are preserved by \seq_set_split:Nnn, and can be removed afterwards using \seq_remove_all:Nn \langle sequence \rangle { {()}}. The \langle delimiter \rangle may not contain \{, \} or \# (assuming \TeX\'s normal category code régime). If the \langle delimiter \rangle is empty, the \langle token list \rangle is split into \langle items \rangle as a \langle token list \rangle.

\seq_concat:NNN \seq_concat:ccc \seq_gconcat:NNN \seq_gconcat:ccc

\seq_if_exist_p:N \seq_if_exist:NTF \seq_if_exist:N \seq_if_exist:c

New: 2012-03-03

Tests whether the \langle sequence \rangle is currently defined. This does not check that the \langle sequence \rangle really is a sequence variable.

2 Appending data to sequences

\seq_put_left:Nn \seq_put_left:(NV|Nv|No|Nx|cn|cV|cv|co|cx) \seq_gput_left:Nn \seq_gput_left:(NV|Nv|No|Nx|cn|cV|cv|co|cx)

Appends the \langle item \rangle to the left of the \langle sequence \rangle.

\seq_put_right:Nn \seq_put_right:(NV|Nv|No|Nx|cn|cV|cv|co|cx) \seq_gput_right:Nn \seq_gput_right:(NV|Nv|No|Nx|cn|cV|cv|co|cx)

Appends the \langle item \rangle to the right of the \langle sequence \rangle.

3 Recovering items from sequences

Items can be recovered from either the left or the right of sequences. For implementation reasons, the actions at the left of the sequence are faster than those acting on the right. These functions all assign the recovered material locally, \textit{i.e.} setting the \langle token list variable \rangle used with \texttt{\tl_set:Nn} and \textit{never} \texttt{\tl_gset:Nn}.

76
\seq_get_left:NN (sequence) (token list variable)\n
Stores the left-most item from a \langle sequence \rangle in the \langle token list variable \rangle without removing it from the \langle sequence \rangle. The \langle token list variable \rangle is assigned locally. If \langle sequence \rangle is empty the \langle token list variable \rangle is set to the special marker \q_no_value.

\seq_get_right:NN (sequence) (token list variable)\n
Stores the right-most item from a \langle sequence \rangle in the \langle token list variable \rangle without removing it from the \langle sequence \rangle. The \langle token list variable \rangle is assigned locally. If \langle sequence \rangle is empty the \langle token list variable \rangle is set to the special marker \q_no_value.

\seq_pop_left:NN (sequence) (token list variable)\n
Pops the left-most item from a \langle sequence \rangle into the \langle token list variable \rangle, i.e. removes the item from the sequence and stores it in the \langle token list variable \rangle. Both of the variables are assigned locally. If \langle sequence \rangle is empty the \langle token list variable \rangle is set to the special marker \q_no_value.

\seq_gpop_left:NN (sequence) (token list variable)\n
Pops the left-most item from a \langle sequence \rangle into the \langle token list variable \rangle, i.e. removes the item from the sequence and stores it in the \langle token list variable \rangle. The \langle sequence \rangle is modified globally, while the assignment of the \langle token list variable \rangle is local. If \langle sequence \rangle is empty the \langle token list variable \rangle is set to the special marker \q_no_value.

\seq_pop_right:NN (sequence) (token list variable)\n
Pops the right-most item from a \langle sequence \rangle into the \langle token list variable \rangle, i.e. removes the item from the sequence and stores it in the \langle token list variable \rangle. Both of the variables are assigned locally. If \langle sequence \rangle is empty the \langle token list variable \rangle is set to the special marker \q_no_value.

\seq_gpop_right:NN (sequence) (token list variable)\n
Pops the right-most item from a \langle sequence \rangle into the \langle token list variable \rangle, i.e. removes the item from the sequence and stores it in the \langle token list variable \rangle. The \langle sequence \rangle is modified globally, while the assignment of the \langle token list variable \rangle is local. If \langle sequence \rangle is empty the \langle token list variable \rangle is set to the special marker \q_no_value.

\seq_item:Nn \langle sequence \rangle \langle integer expression \rangle\n
Indexing items in the \langle sequence \rangle from 1 at the top (left), this function evaluates the \langle integer expression \rangle and leaves the appropriate item from the sequence in the input stream. If the \langle integer expression \rangle is negative, indexing occurs from the bottom (right) of the sequence. If the \langle integer expression \rangle is larger than the number of items in the \langle sequence \rangle (as calculated by \seq_count:N) then the function expands to nothing.

\textbf{TeX hackers note:} The result is returned within the \texttt{\unexpanded} primitive \texttt{\exp_not:n}, which means that the \langle item \rangle does not expand further when appearing in an \texttt{x-type} argument expansion.
\seq_rand_item:N \seq_rand_item:C *

Selects a pseudo-random item of the \textit{sequence}. If the \textit{sequence} is empty the result is empty. This is not available in older versions of Xe\TeX{}.

\textbf{TeXhacker note:} The result is returned within the \texttt{\exp_not:n}, which means that the \textit{item} does not expand further when appearing in an \texttt{x}-type argument expansion.

4 Recovering values from sequences with branching

The functions in this section combine tests for non-empty sequences with recovery of an item from the sequence. They offer increased readability and performance over separate testing and recovery phases.

\seq_get_left:NN \seq_get_left:cNTF

If the \textit{sequence} is empty, leaves the \textit{false code} in the input stream. The value of the \textit{token list variable} is not defined in this case and should not be relied upon. If the \textit{sequence} is non-empty, stores the left-most item from the \textit{sequence} in the \textit{token list variable} without removing it from the \textit{sequence}, then leaves the \textit{true code} in the input stream. The \textit{token list variable} is assigned locally.

\seq_get_right:NN \seq_get_right:cNTF

If the \textit{sequence} is empty, leaves the \textit{false code} in the input stream. The value of the \textit{token list variable} is not defined in this case and should not be relied upon. If the \textit{sequence} is non-empty, stores the right-most item from the \textit{sequence} in the \textit{token list variable} without removing it from the \textit{sequence}, then leaves the \textit{true code} in the input stream. The \textit{token list variable} is assigned locally.

\seq_pop_left:NN \seq_pop_left:cNTF

If the \textit{sequence} is empty, leaves the \textit{false code} in the input stream. The value of the \textit{token list variable} is not defined in this case and should not be relied upon. If the \textit{sequence} is non-empty, pops the left-most item from the \textit{sequence} in the \textit{token list variable}, i.e. removes the item from the \textit{sequence}, then leaves the \textit{true code} in the input stream. Both the \textit{sequence} and the \textit{token list variable} are assigned locally.

\seq_gpop_left:NN \seq_gpop_left:cNTF

If the \textit{sequence} is empty, leaves the \textit{false code} in the input stream. The value of the \textit{token list variable} is not defined in this case and should not be relied upon. If the \textit{sequence} is non-empty, pops the left-most item from the \textit{sequence} in the \textit{token list variable}, i.e. removes the item from the \textit{sequence}, then leaves the \textit{true code} in the input stream. The \textit{sequence} is modified globally, while the \textit{token list variable} is assigned locally.
5 Modifying sequences

While sequences are normally used as ordered lists, it may be necessary to modify the content. The functions here may be used to update sequences, while retaining the order of the unaffected entries.

\texttt{seq\_remove\_duplicates:N} \langle\text{item}\rangle \langle\text{sequence}\rangle

Removes duplicate items from the \langle\text{sequence}\rangle, leaving the left most copy of each item in the \langle\text{sequence}\rangle. The \langle\text{item}\rangle comparison takes place on a token basis, as for \texttt{tl\_if\_eq:nTF}.

\textbf{\textit{\LaTeX} hackers note:} This function iterates through every item in the \langle\text{sequence}\rangle and does a comparison with the \langle\text{items}\rangle already checked. It is therefore relatively slow with large sequences.

\texttt{seq\_remove\_all:Nn} \langle\text{item}\rangle \langle\text{sequence}\rangle

Removes every occurrence of \langle\text{item}\rangle from the \langle\text{sequence}\rangle. The \langle\text{item}\rangle comparison takes place on a token basis, as for \texttt{tl\_if\_eq:nTF}.

\texttt{seq\_reverse:N} \langle\text{sequence}\rangle

Reverses the order of the items stored in the \langle\text{sequence}\rangle.

\texttt{seq\_sort:Nn} \langle\text{comparison code}\rangle \langle\text{sequence}\rangle

Sorts the items in the \langle\text{sequence}\rangle according to the \langle\text{comparison code}\rangle, and assigns the result to \langle\text{sequence}\rangle. The details of sorting comparison are described in Section 1.
\seq_shuffle:N \langle seq \text{ var} \rangle
\seq_gshuffle:N \langle seq \text{ var} \rangle

Sets the \langle seq \text{ var} \rangle to the result of placing the items of the \langle seq \text{ var} \rangle in a random order. Each item is (roughly) as likely to end up in any given position.

\textbf{\TeX hackers note:} For sequences with more than 13 items or so, only a small proportion of all possible permutations can be reached, because the random seed \sys_rand_seed: only has 28-bits. The use of \toks internally means that sequences with more than 32767 or 65535 items (depending on the engine) cannot be shuffled.

\section{Sequence conditionals}
\seq_if_empty_p:N \langle sequence \rangle
\seq_if_empty_p:c \langle sequence \rangle
\seq_if_empty:NTF \langle sequence \rangle \{ \langle true \text{ code} \rangle \} \{ \langle false \text{ code} \rangle \}

Tests if the \langle sequence \rangle is empty (containing no items).

\seq_if_in:NnTF \langle sequence \rangle \{ \langle item \rangle \} \{ \langle true \text{ code} \rangle \} \{ \langle false \text{ code} \rangle \}

Tests if the \langle item \rangle is present in the \langle sequence \rangle.

\section{Mapping to sequences}
All mappings are done at the current group level, \textit{i.e.} any local assignments made by the \langle function \rangle or \langle code \rangle discussed below remain in effect after the loop.
\seq_map_function:NN \langle sequence \rangle \langle function \rangle
\seq_map_token:Nn \langle sequence \rangle \langle \text{inline function} \rangle

Applies \langle function \rangle to every \langle item \rangle stored in the \langle sequence \rangle. The \langle function \rangle will receive one argument for each iteration. The \langle items \rangle are returned from left to right. To pass further arguments to the \langle function \rangle, see \seq_map_tokens:Nn. The function \seq_map_inline:Nn is faster than \seq_map_function:NN for sequences with more than about 10 items.

\seq_map_inline:Nn \langle sequence \rangle \langle \text{inline function} \rangle

Applies \langle inline function \rangle to every \langle item \rangle stored within the \langle sequence \rangle. The \langle inline function \rangle should consist of code which will receive the \langle item \rangle as \#1. The \langle items \rangle are returned from left to right.
Analogue of \seq_map_function:NN which maps several tokens instead of a single function. The \code{} receives each item in the \sequence{} as two trailing brace groups. For instance,

\begin{verbatim}
\seq_map_tokens:Nn \l_my_seq { \prg_replicate:nn { 2 } }
\end{verbatim}

expands to twice each item in the \sequence{}: for each item in \l_my_seq the function \prg_replicate:nn receives 2 and \item{} as its two arguments. The function \seq_map_inline:Nn is typically faster but is not expandable.

Stores each \item{} of the \sequence{} in turn in the (token list) \variable{} and applies the \code{}. The \code{} will usually make use of the \variable{}, but this is not enforced. The assignments to the \variable{} are local. Its value after the loop is the last \item{} in the \sequence{}, or its original value if the \sequence{} is empty. The \items{} are returned from left to right.

Used to terminate a \seq_map_... function before all entries in the \sequence{} have been processed. This normally takes place within a conditional statement, for example

\begin{verbatim}
\seq_map_inline:Nn \l_my_seq
    { \str_if_eq:nnTF { #1 } { bingo } { \seq_map_break: } % Do something useful }
\end{verbatim}

Use outside of a \seq_map_... scenario leads to low level \TeX{} errors.

\TeX{}hackers note: When the mapping is broken, additional tokens may be inserted before further items are taken from the input stream. This depends on the design of the mapping function.
\seq_map_break:n \seq_map_break:n \{<code>\}

Used to terminate a \seq_map_inline:Nn \l_my_seq
{ \str_if_eq:nnTF { #1 } { bingo } { \seq_map_break:n \{<code>\} } }
{ % Do something useful }
}

Use outside of a \seq_map_inline:Nn scenario leads to low level \TeX errors.

\textbf{\TeXhackers note:} When the mapping is broken, additional tokens may be inserted before the \(\langle code \rangle\) is inserted into the input stream. This depends on the design of the mapping function.

\seq_count:N \seq_count:N \langle sequence \rangle

Leaves the number of items in the \(\langle sequence \rangle\) in the input stream as an \(\langle integer \ denotation \rangle\). The total number of items in a \(\langle sequence \rangle\) includes those which are empty and duplicates, i.e. every item in a \(\langle sequence \rangle\) is unique.

8 Using the content of sequences directly

\seq_use:Nnnn \seq_set_split:Nnn \l_tmpa_seq { | } { a | b | c | {de} | f }
\seq_use:Nnnn \l_tmpa_seq { -and- } { ,~ } { ,~and~ }{ ,~and- }

inserts “a, b, c, de, and f” in the input stream. The first separator argument is not used in this case because the sequence has more than 2 items.

\textbf{\TeXhackers note:} The result is returned within the \unexpanded primitive \(\exp_not:n\), which means that the \(\langle items \rangle\) do not expand further when appearing in an x-type argument expansion.
\seq_use:Nn \seq_use:cn * New: 2013-05-26

\seq_use:Nn \seq_var \seq_split \{ \seq_separator \}
Places the contents of the \seq_var in the input stream, with the \seq_separator between the items. If the sequence has a single item, it is placed in the input stream with no \seq_separator, and an empty sequence produces no output. An error is raised if the variable does not exist or if it is invalid.

For example,

\seq_set_split:Nnn \l_tmpa_seq \{ | \} \{ a | b | c | \{ de \} | f \}
\seq_use:Nn \l_tmpa_seq \{ \text{and} \}

inserts “a and b and c and de and f” in the input stream.

\TeXhackers note: The result is returned within the \unexpanded primitive (\exp_not:n), which means that the \items do not expand further when appearing in an x-type argument expansion.

9 Sequences as stacks

Sequences can be used as stacks, where data is pushed to and popped from the top of the sequence. (The left of a sequence is the top, for performance reasons.) The stack functions for sequences are not intended to be mixed with the general ordered data functions detailed in the previous section: a sequence should either be used as an ordered data type or as a stack, but not in both ways.

\seq_get:NN \seq_get:cN Updated: 2012-05-14
\seq_pop:NN \seq_pop:cN Updated: 2012-05-14
\seq_gpop:NN \seq_gpop:cN Updated: 2012-05-14
\seq_get:NNTF \seq_get:NTF Updated: 2012-05-19

\seq_get:NN \seq_get:cN
Reads the top item from a \sequence into the \token_list_variable without removing it from the \sequence. The \token_list_variable is assigned locally. If \sequence is empty the \token_list_variable is set to the special marker \q_no_value.

\seq_pop:NN \seq_pop:cN
Pops the top item from a \sequence into the \token_list_variable. Both of the variables are assigned locally. If \sequence is empty the \token_list_variable is set to the special marker \q_no_value.

\seq_gpop:NN \seq_gpop:cN
Pops the top item from a \sequence into the \token_list_variable. The \sequence is modified globally, while the \token_list_variable is assigned locally. If \sequence is empty the \token_list_variable is set to the special marker \q_no_value.

\seq_get:NNTF \seq_get:NTF
If the \sequence is empty, leaves the \false_code in the input stream. The value of the \token_list_variable is not defined in this case and should not be relied upon. If the \sequence is non-empty, stores the top item from a \sequence in the \token_list_variable without removing it from the \sequence. The \token_list_variable is assigned locally.
If the (sequence) is empty, leaves the (false code) in the input stream. The value of the (token list variable) is not defined in this case and should not be relied upon. If the (sequence) is non-empty, pops the top item from the (sequence) in the (token list variable), i.e. removes the item from the (sequence). Both the (sequence) and the (token list variable) are assigned locally.

If the (sequence) is empty, leaves the (false code) in the input stream. The value of the (token list variable) is not defined in this case and should not be relied upon. If the (sequence) is non-empty, pops the top item from the (sequence) in the (token list variable), i.e. removes the item from the (sequence). The (sequence) is modified globally, while the (token list variable) is assigned locally.

10 Sequences as sets

Sequences can also be used as sets, such that all of their items are distinct. Usage of sequences as sets is not currently widespread, hence no specific set function is provided. Instead, it is explained here how common set operations can be performed by combining several functions described in earlier sections. When using sequences to implement sets, one should be careful not to rely on the order of items in the sequence representing the set.

Sets should not contain several occurrences of a given item. To make sure that a (sequence variable) only has distinct items, use \texttt{\seq_remove_duplicates:N} (sequence variable). This function is relatively slow, and to avoid performance issues one should only use it when necessary.

Some operations on a set (seq var) are straightforward. For instance, \texttt{\seq_count:N} (seq var) expands to the number of items, while \texttt{\seq_if_in:NnTF} (seq var) \{\texttt{\texttt{\texttt{\texttt{\texttt{(item)}}}}\}}} tests if the (item) is in the set.

Adding an (item) to a set (seq var) can be done by appending it to the (seq var) if it is not already in the (seq var):

\texttt{\seq_if_in:NnF} (seq var) \{\texttt{\texttt{\texttt{\texttt{\texttt{(item)}}}}\}}} \{ \texttt{\seq_put_right:Nn} (seq var) \{\texttt{\texttt{\texttt{\texttt{\texttt{(item)}}}}\}}} \}

Removing an (item) from a set (seq var) can be done using \texttt{\seq_remove_all:N},

\texttt{\seq_remove_all:N} (seq var) \{\texttt{\texttt{\texttt{\texttt{\texttt{(item)}}}}\}}

The intersection of two sets (seq var\textsubscript{1}) and (seq var\textsubscript{2}) can be stored into (seq var\textsubscript{3}) by collecting items of (seq var\textsubscript{1}) which are in (seq var\textsubscript{2}).
\seq_clear:N \seq_var_3
\seq_map_inline:Nn \seq_var_1
\seq_if_in:NnT \seq_var_2 \#1
\seq_put_right:Nn \seq_var_3 \#1

The code as written here only works if \seq_var_3 is different from the other two sequence variables. To cover all cases, items should first be collected in a sequence \l__\pkg\_internal_seq, then \seq_var_3 should be set equal to this internal sequence.

The same remark applies to other set functions.

The union of two sets \seq_var_1 and \seq_var_2 can be stored into \seq_var_3 through
\seq_concat:NNN \seq_var_3 \seq_var_1 \seq_var_2
\seq_remove_duplicates:N \seq_var_3

or by adding items to (a copy of) \seq_var_1 one by one
\seq_set_eq:NN \seq_var_3 \seq_var_1
\seq_map_inline:Nn \seq_var_2
\seq_if_in:NnF \seq_var_3 \#1
\seq_put_right:Nn \seq_var_3 \#1

The second approach is faster than the first when the \seq_var_2 is short compared to \seq_var_1.

The difference of two sets \seq_var_1 and \seq_var_2 can be stored into \seq_var_3 by removing items of the \seq_var_2 from (a copy of) the \seq_var_1 one by one.
\seq_set_eq:NN \seq_var_3 \seq_var_1
\seq_remove_all:NN \seq_var_2 \seq_var_3

The symmetric difference of two sets \seq_var_1 and \seq_var_2 can be stored into \seq_var_3 by computing the difference between \seq_var_1 and \seq_var_2 and storing the result as \l__\pkg\_internal_seq, then the difference between \seq_var_2 and \seq_var_1, and finally concatenating the two differences to get the symmetric differences.
\seq_set_eq:NN \l__\pkg\_internal_seq \seq_var_1
\seq_set_eq:NN \seq_var_3 \seq_var_2
\seq_remove_all:NN \seq_var_2 \seq_var_3
\seq_map_inline:Nn \seq_var_1
\seq_remove_all:NN \seq_var_3 \seq_var_1
\seq_concat:NNN \seq_var_3 \seq_var_3 \l__\pkg\_internal_seq

\c_empty_seq

11 Constant and scratch sequences
Scratch sequences for local assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

Scratch sequences for global assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

\section*{12 Viewing sequences}

\begin{itemize}
\item \seq_show:N
\end{itemize}

\seq_show:N \langle sequence \rangle

Displays the entries in the \langle sequence \rangle in the terminal.

\begin{itemize}
\item \seq_log:N
\end{itemize}

\seq_log:N \langle sequence \rangle

Writes the entries in the \langle sequence \rangle in the log file.
Part XI

The l3int package

Integers

Calculation and comparison of integer values can be carried out using literal numbers, \texttt{int}
registers, constants and integers stored in token list variables. The standard operators
+, -, / and * and parentheses can be used within such expressions to carry arithmetic
operations. This module carries out these functions on integer expressions ("intexpr").
1 Integer expressions

\int_eval:n \{ (integer expression) \}

Evaluates the \textit{(integer expression)} and leaves the result in the input stream as an integer denotation: for positive results an explicit sequence of decimal digits not starting with 0, for negative results - followed by such a sequence, and 0 for zero. The \textit{(integer expression)} should consist, after expansion, of +, -, *, /, (, ) and of course integer operands. The result is calculated by applying standard mathematical rules with the following peculiarities:

- / denotes division rounded to the closest integer with ties rounded away from zero;
- there is an error and the overall expression evaluates to zero whenever the absolute value of any intermediate result exceeds $2^{31} - 1$, except in the case of scaling operations $a \times b / c$, for which $a \times b$ may be arbitrarily large;
- parentheses may not appear after unary + or -, namely placing +( or -( at the start of an expression or after +, -, *, / or ( leads to an error.

Each integer operand can be either an integer variable (with no need for \texttt{\int_use:N}) or an integer denotation. For example both

\begin{verbatim}
\int_eval:n { 5 + 4 * 3 - ( 3 + 4 * 5 ) }
\end{verbatim}

and

\begin{verbatim}
\tl_new:N \l_my_tl
\tl_set:Nn \l_my_tl { 5 }
\int_new:N \l_my_int
\int_set:Nn \l_my_int { 4 }
\int_eval:n { \l_my_tl + \l_my_int * 3 - ( 3 + 4 * 5 ) }
\end{verbatim}

evaluate to -6 because \texttt{\l_my_tl} expands to the integer denotation 5. As the \textit{(integer expression)} is fully expanded from left to right during evaluation, fully expandable and restricted-expandable functions can both be used, and \texttt{\exp_not:n} and its variants have no effect while \texttt{\exp_not:N} may incorrectly interrupt the expression.

\textbf{\TeX{}hackers note:} Exactly two expansions are needed to evaluate \texttt{\int_eval:n}. The result is not an \textit{(internal integer)}, and therefore requires suitable termination if used in a \TeX{}-style integer assignment.

As all \TeX{} integers, integer operands can also be dimension or skip variables, converted to integers in \texttt{sp}, or octal numbers given as ' followed by digits other than 8 and 9, or hexadecimal numbers given as " followed by digits or upper case letters from A to F, or the character code of some character or one-character control sequence, given as '{char}'.

88
\int_eval:w \int_eval:w ⟨integer expression⟩

Evaluates the ⟨integer expression⟩ as described for \int_eval:n. The end of the expression is the first token encountered that cannot form part of such an expression. If that token is \scan_stop: it is removed, otherwise not. Spaces do not terminate the expression. However, spaces terminate explicit integers, and this may terminate the expression: for instance, \int_eval:w 1_{\uparrow}1_{\uparrow}9 expands to 29 since the digit 9 is not part of the expression.

\int_sign:n \int_sign:n \{⟨intexpr⟩\}

Evaluates the ⟨integer expression⟩ then leaves 1 or 0 or −1 in the input stream according to the sign of the result.

\int_abs:n \int_abs:n \{⟨integer expression⟩\}

Evaluates the ⟨integer expression⟩ as described for \int_eval:n and leaves the absolute value of the result in the input stream as an ⟨integer denotation⟩ after two expansions.

\int_div_round:nn \int_div_round:nn \{⟨intexpr⟩\} \{⟨intexpr⟩\}

Evaluates the two ⟨integer expressions⟩ as described earlier, then divides the first value by the second, and rounds the result to the closest integer. Ties are rounded away from zero. Note that this is identical to using / directly in an ⟨integer expression⟩. The result is left in the input stream as an ⟨integer denotation⟩ after two expansions.

\int_max:nn \int_max:nn \{⟨intexpr⟩\} \{⟨intexpr⟩\}
\int_min:nn \int_min:nn \{⟨intexpr⟩\} \{⟨intexpr⟩\}

Evaluates the ⟨integer expressions⟩ as described for \int_eval:n and leaves either the larger or smaller value in the input stream as an ⟨integer denotation⟩ after two expansions.

\int_mod:nn \int_mod:nn \{⟨intexpr⟩\} \{⟨intexpr⟩\}

Evaluates the two ⟨integer expressions⟩ as described earlier, then calculates the integer remainder of dividing the first expression by the second. This is obtained by subtracting \int_div_truncate:nn \{⟨intexpr⟩\} \{⟨intexpr⟩\} times ⟨intexpr⟩2 from ⟨intexpr⟩1. Thus, the result has the same sign as ⟨intexpr⟩1 and its absolute value is strictly less than that of ⟨intexpr⟩2. The result is left in the input stream as an ⟨integer denotation⟩ after two expansions.

2 Creating and initialising integers

\int_new:N \int_new:N \{⟨integer⟩\}

Creates a new ⟨integer⟩ or raises an error if the name is already taken. The declaration is global. The ⟨integer⟩ is initially equal to 0.
\int_const:Nn
\int_const:cn

\int_zero:N

\int_gincr:N
\int_gincr:c

\int_set_eq:NN \langle integer \rangle \{ \langle integer expression \rangle \}

\int_const:Nn \langle integer \rangle \{ \langle integer expression \rangle \}

Creates a new constant \langle integer \rangle or raises an error if the name is already taken. The value of the \langle integer \rangle is set globally to the \langle integer expression \rangle.

\int_zero:N \langle integer \rangle

Sets \langle integer \rangle to 0.

\int_zero_new:N \langle integer \rangle

Ensures that the \langle integer \rangle exists globally by applying \int_new:N if necessary, then applies \int_(g)zero:N to leave the \langle integer \rangle set to zero.

\int_set_eq:NN \langle integer1 \rangle \{ \langle integer2 \rangle \}

Sets the content of \langle integer1 \rangle equal to that of \langle integer2 \rangle.

\int_if_exist_p:N \langle int \rangle
\int_if_exist_p:c \langle int \rangle
\int_if_exist:NTF \langle int \rangle \{ \langle true code \rangle \} \{ \langle false code \rangle \}

Tests whether the \langle int \rangle is currently defined. This does not check that the \langle int \rangle really is an integer variable.

3 Setting and incrementing integers

\int_add:Nn \langle integer \rangle \{ \langle integer expression \rangle \}

\int_add:Nn \langle integer \rangle \{ \langle integer expression \rangle \}

Adds the result of the \langle integer expression \rangle to the current content of the \langle integer \rangle.

\int_decr:N \langle integer \rangle

Decreases the value stored in \langle integer \rangle by 1.

\int_incr:N \langle integer \rangle

Increases the value stored in \langle integer \rangle by 1.
\int_set:Nn \int_set:cn \int_gset:Nn \int_gset:cn

Sets \textit{integer} to the value of \textit{integer expression}, which must evaluate to an integer (as described for \texttt{\int_eval:n}).

\int_sub:Nn \int_sub:cn \int_gsub:Nn \int_gsub:cn

Subtracts the result of the \textit{integer expression} from the current content of the \textit{integer}.

\section{Using integers}

\int_use:N * \int_use:c *

Recovers the content of an \textit{integer} and places it directly in the input stream. An error is raised if the variable does not exist or if it is invalid. Can be omitted in places where an \textit{integer} is required (such as in the first and third arguments of \texttt{\int_compare:nNnTF}).

\textbf{\LaTeX} hackers note: \texttt{\int_use:N} is the \TeX{} primitive \texttt{\the}: this is one of several \LaTeX{} names for this primitive.

\section{Integer expression conditionals}

\int_compare_p:nNn \int_compare:nNnTF

This function first evaluates each of the \textit{integer expressions} as described for \texttt{\int_eval:n}. The two results are then compared using the \textit{relation}:

\begin{itemize}
  \item Equal =
  \item Greater than >
  \item Less than <
\end{itemize}

This function is less flexible than \texttt{\int_compare:nTF} but around 5 times faster.
\int_compare_p:n
\int_compare:nTF

This function evaluates the \textit{integer expressions} as described for \texttt{\int_eval:n} and compares consecutive result using the corresponding \textit{relation}, namely it compares \texttt{\intexpr_1} and \texttt{\intexpr_2} using the \texttt{\relation_1}, then \texttt{\intexpr_2} and \texttt{\intexpr_3} using the \texttt{\relation_2}, until finally comparing \texttt{\intexpr_N} and \texttt{\intexpr_{N+1}} using the \texttt{\relation_N}. The test yields \texttt{true} if all comparisons are \texttt{true}. Each \textit{integer expression} is evaluated only once, and the evaluation is lazy, in the sense that if one comparison is \texttt{false}, then no other \textit{integer expression} is evaluated and no other comparison is performed. The \textit{relations} can be any of the following:

\begin{itemize}
  \item Equal \quad = \text{ or } ==
  \item Greater than or equal to \quad >=
  \item Greater than \quad >
  \item Less than or equal to \quad <=
  \item Less than \quad <
  \item Not equal \quad !=
\end{itemize}

This function is more flexible than \texttt{\int_compare:nNnTF} but around 5 times slower.
This function evaluates the \textit{test integer expression} and compares this in turn to each of the \textit{integer expression cases}. If the two are equal then the associated \textit{code} is left in the input stream and other cases are discarded. If any of the cases are matched, the \textit{true code} is also inserted into the input stream (after the code for the appropriate case), while if none match then the \textit{false code} is inserted. The function \texttt{\textbackslash int\_case:nn}, which does nothing if there is no match, is also available. For example

\begin{verbatim}
\texttt{\textbackslash int\_case:nnF} \{ 2 * 5 \}
{  5 }  \{ Small \}
{ 4 + 6 }  \{ Medium \}
{ -2 * 10 } \{ Negative \}
{ No idea! }
\end{verbatim}

leaves “Medium” in the input stream.

\section{6 Integer expression loops}

\begin{verbatim}
\texttt{\textbackslash int\_do\_until:nNnn} \{ \texttt{\textbackslash int\_do\_while:nNnn} \}
\end{verbatim}

Places the \textit{code} in the input stream for \TeX{} to process, and then evaluates the relationship between the two \textit{integer expressions} as described for \texttt{\textbackslash int\_compare:nNnTF}. If the test is \texttt{false} then the \textit{code} is inserted into the input stream again and a loop occurs until the \textit{relation} is \texttt{true}.

\begin{verbatim}
\texttt{\textbackslash int\_do\_while:nNnn} \{ \texttt{\textbackslash int\_do\_until:nNnn} \}
\end{verbatim}

Places the \textit{code} in the input stream for \TeX{} to process, and then evaluates the relationship between the two \textit{integer expressions} as described for \texttt{\textbackslash int\_compare:nNnTF}. If the test is \texttt{true} then the \textit{code} is inserted into the input stream again and a loop occurs until the \textit{relation} is \texttt{false}.
\int_until_do:nNnn \{\langle\text{integer expression}\rangle\} \{\langle\text{relation}\rangle\} \{\langle\text{code}\rangle\}

Evaluates the relationship between the two \langle\text{integer expressions}\rangle as described for \texttt{\int_compare:nTF}, and then places the \langle\text{code}\rangle in the input stream if the \langle\text{relation}\rangle is \texttt{false}. After the \langle\text{code}\rangle has been processed by \TeX{} the test is repeated, and a loop occurs until the test is \texttt{true}.

\int_until_do:nNnn

\int_until_do:nNnn \{\langle\text{integer relation}\rangle\} \{\langle\text{code}\rangle\}

Places the \langle\text{code}\rangle in the input stream for \TeX{} to process, and then evaluates the \langle\text{integer relation}\rangle as described for \texttt{\int_compare:nTF}. If the test is \texttt{false} then the \langle\text{code}\rangle is inserted into the input stream again and a loop occurs until the \langle\text{relation}\rangle is \texttt{true}.

\int_until_do:nNnn

\int_until_do:nNnn \{\langle\text{integer relation}\rangle\} \{\langle\text{code}\rangle\}

Evaluates the \langle\text{integer relation}\rangle as described for \texttt{\int_compare:nTF}, and then places the \langle\text{code}\rangle in the input stream if the \langle\text{relation}\rangle is \texttt{false}. After the \langle\text{code}\rangle has been processed by \TeX{} the test is repeated, and a loop occurs until the test is \texttt{true}.

\int_until_do:nNnn

\int_until_do:nNnn \{\langle\text{integer relation}\rangle\} \{\langle\text{code}\rangle\}

Evaluates the \langle\text{integer relation}\rangle as described for \texttt{\int_compare:nTF}, and then places the \langle\text{code}\rangle in the input stream if the \langle\text{relation}\rangle is \texttt{true}. After the \langle\text{code}\rangle has been processed by \TeX{} the test is repeated, and a loop occurs until the test is \texttt{false}. Updated: 2013-01-13
7 Integer step functions

\int_step_function:nnN \{ (final value) \} \{ function \}
\int_step_function:nnN \{ (initial value) \} \{ (final value) \} \{ function \}
\int_step_function:nnN \{ (initial value) \} \{ (step) \} \{ (final value) \} \{ function \}

This function first evaluates the \( (initial value) \), \( (step) \) and \( (final value) \), all of which should be integer expressions. The \( (function) \) is then placed in front of each \( (value) \) from the \( (initial value) \) to the \( (final value) \) in turn (using \( (step) \) between each \( (value) \)). The \( (step) \) must be non-zero. If the \( (step) \) is positive, the loop stops when the \( (value) \) becomes larger than the \( (final value) \). If the \( (step) \) is negative, the loop stops when the \( (value) \) becomes smaller than the \( (final value) \). The \( (function) \) should absorb one numerical argument. For example

\begin{verbatim}
\cs_set:Npn \my_func:n #1 { \[I saw #1\] \quad }
\int_step_function:nnN \{ 1 \} \{ 1 \} \{ 5 \} \my_func:n
\end{verbatim}

would print

\[ I \text{ saw } 1 \quad I \text{ saw } 2 \quad I \text{ saw } 3 \quad I \text{ saw } 4 \quad I \text{ saw } 5 \]

The functions \( \int_step_function:nnN \) and \( \int_step_function:nnN \) both use a fixed \( (step) \) of 1, and in the case of \( \int_step_function:nnN \) the \( (initial value) \) is also fixed as 1. These functions are provided as simple short-cuts for code clarity.

\int_step_inline:n { (final value) \} \{ (code) \}
\int_step_inline:n { (initial value) \} \{ (final value) \} \{ (code) \}
\int_step_inline:n { (initial value) \} \{ (step) \} \{ (final value) \} \{ (code) \}

This function first evaluates the \( (initial value) \), \( (step) \) and \( (final value) \), all of which should be integer expressions. Then for each \( (value) \) from the \( (initial value) \) to the \( (final value) \) in turn (using \( (step) \) between each \( (value) \)), the \( (code) \) is inserted into the input stream with \#1 replaced by the current \( (value) \). Thus the \( (code) \) should define a function of one argument (\#1).

The functions \( \int_step_inline:n \) and \( \int_step_inline:n \) both use a fixed \( (step) \) of 1, and in the case of \( \int_step_inline:n \) the \( (initial value) \) is also fixed as 1. These functions are provided as simple short-cuts for code clarity.

\int_step_variable:nnN \{ (final value) \} \{tl var\} \{ (code) \}
\int_step_variable:nnN \{ (initial value) \} \{ (final value) \} \{tl var\} \{ (code) \}
\int_step_variable:nnN \{ (initial value) \} \{ (step) \} \{ (final value) \} \{tl var\} \{ (code) \}

This function first evaluates the \( (initial value) \), \( (step) \) and \( (final value) \), all of which should be integer expressions. Then for each \( (value) \) from the \( (initial value) \) to the \( (final value) \) in turn (using \( (step) \) between each \( (value) \)), the \( (code) \) is inserted into the input stream, with the \( (tl var) \) defined as the current \( (value) \). Thus the \( (code) \) should make use of the \( (tl var) \).

The functions \( \int_step_variable:nnN \) and \( \int_step_variable:nnN \) both use a fixed \( (step) \) of 1, and in the case of \( \int_step_variable:nnN \) the \( (initial value) \) is also fixed as 1. These functions are provided as simple short-cuts for code clarity.
8 Formatting integers

Integers can be placed into the output stream with formatting. These conversions apply to any integer expressions.

\int_to_arabic:n \{ \langle \text{integer expression} \rangle \}

Places the value of the \langle \text{integer expression} \rangle in the input stream as digits, with category code 12 (other).

\int_to_alph:n \{ \langle \text{integer expression} \rangle \}

Evaluates the \langle \text{integer expression} \rangle and converts the result into a series of letters, which are then left in the input stream. The conversion rule uses the 26 letters of the English alphabet, in order, adding letters when necessary to increase the total possible range of representable numbers. Thus

\int_to_alph:n \{ 1 \}
 places a in the input stream,

\int_to_alph:n \{ 26 \}
 is represented as z and

\int_to_alph:n \{ 27 \}
 is converted to aa. For conversions using other alphabets, use \int_to_symbols:nnn to define an alphabet-specific function. The basic \int_to_alph:n and \int_to_Alph:n functions should not be modified. The resulting tokens are digits with category code 12 (other) and letters with category code 11 (letter).

\int_to_symbols:nnn \{ \langle \text{integer expression} \rangle \} \{ \langle \text{total symbols} \rangle \}
 \{ \langle \text{value to symbol mapping} \rangle \}

This is the low-level function for conversion of an \langle integer expression \rangle into a symbolic form (often letters). The \langle total symbols \rangle available should be given as an integer expression. Values are actually converted to symbols according to the \langle value to symbol mapping \rangle. This should be given as \langle total symbols \rangle pairs of entries, a number and the appropriate symbol. Thus the \int_to_alph:n function is defined as

\cs_new:Npn \int_to_alph:n #1
 { \int_to_symbols:nnn {#1} \{ 26 \}
     \{ 1 \} \{ a \}
     \{ 2 \} \{ b \}
     \ldots
     \{ 26 \} \{ z \}
 }
\int_to_bin:n \{\text{integer expression}\} 
Calculates the value of the \textit{(integer expression)} and places the binary representation of the result in the input stream.

\int_to_hex:n \{\text{integer expression}\} 
\int_to_Hex:n 
Calculates the value of the \textit{(integer expression)} and places the hexadecimal (base 16) representation of the result in the input stream. Letters are used for digits beyond 9: lower case letters for \texttt{\int_to_hex:n} and upper case ones for \texttt{\int_to_Hex:n}. The resulting tokens are digits with category code 12 (other) and letters with category code 11 (letter).

\int_to_oct:n \{\text{integer expression}\} 
Calculates the value of the \textit{(integer expression)} and places the octal (base 8) representation of the result in the input stream. The resulting tokens are digits with category code 12 (other) and letters with category code 11 (letter).

\int_to_base:nn \{\text{integer expression}\} \{\text{base}\} 
\int_to_Base:nn 
Calculates the value of the \textit{(integer expression)} and converts it into the appropriate representation in the \textit{(base)}; the latter may be given as an integer expression. For bases greater than 10 the higher “digits” are represented by letters from the English alphabet: lower case letters for \texttt{\int_to_base:n} and upper case ones for \texttt{\int_to_Base:n}. The maximum \textit{(base)} value is 36. The resulting tokens are digits with category code 12 (other) and letters with category code 11 (letter).

\textbf{\TeX}hackers note: This is a generic version of \texttt{\int_to_bin:n}, etc.

\int_to_roman:n \{\text{integer expression}\} 
\int_to_Roman:n 
Places the value of the \textit{(integer expression)} in the input stream as Roman numerals, either lower case \texttt{\int_to_roman:n} or upper case \texttt{\int_to_Roman:n}. If the value is negative or zero, the output is empty. The Roman numerals are letters with category code 11 (letter). The letters used are \texttt{mdclxvi}, repeated as needed: the notation with bars (such as \texttt{\=v} for 5000) is \textit{not} used. For instance \texttt{\int_to_roman:n \{ 8249 \}} expands to \texttt{mmmmmmccxlix}.

\textbf{9 Converting from other formats to integers}

\int_from_alph:n \{\text{letters}\} 
Converts the \textit{(letters)} into the integer (base 10) representation and leaves this in the input stream. The \textit{(letters)} are first converted to a string, with no expansion. Lower and upper case letters from the English alphabet may be used, with “a” equal to 1 through to “z” equal to 26. The function also accepts a leading sign, made of + and -. This is the inverse function of \texttt{\int_to_alph:n} and \texttt{\int_to_Alph:n}. 

\texttt{\textbackslash int\_from\_bin:n} \* \texttt{\textbackslash int\_from\_bin:n \{\textlangle\text{binary number}\}\}}\textbackslash n

New: 2014-02-11
Updated: 2014-08-25

Converts the \langle binary number \rangle into the integer (base 10) representation and leaves this in the input stream. The \langle binary number \rangle is first converted to a string, with no expansion. The function accepts a leading sign, made of + and -, followed by binary digits. This is the inverse function of \texttt{\textbackslash int\_to\_bin:n}.

\texttt{\textbackslash int\_from\_hex:n} \* \texttt{\textbackslash int\_from\_hex:n \{\textlangle\text{hexadecimal number}\}\}}\textbackslash n

New: 2014-02-11
Updated: 2014-08-25

Converts the \langle hexadecimal number \rangle into the integer (base 10) representation and leaves this in the input stream. Digits greater than 9 may be represented in the \langle hexadecimal number \rangle by upper or lower case letters. The \langle hexadecimal number \rangle is first converted to a string, with no expansion. The function also accepts a leading sign, made of + and -. This is the inverse function of \texttt{\textbackslash int\_to\_hex:n} and \texttt{\textbackslash int\_to\_Hex:n}.

\texttt{\textbackslash int\_from\_oct:n} \* \texttt{\textbackslash int\_from\_oct:n \{\textlangle\text{octal number}\}\}}\textbackslash n

New: 2014-02-11
Updated: 2014-08-25

Converts the \langle octal number \rangle into the integer (base 10) representation and leaves this in the input stream. The \langle octal number \rangle is first converted to a string, with no expansion. The function accepts a leading sign, made of + and -, followed by octal digits. This is the inverse function of \texttt{\textbackslash int\_to\_oct:n}.

\texttt{\textbackslash int\_from\_roman:n} \* \texttt{\textbackslash int\_from\_roman:n \{\textlangle\text{roman numeral}\}\}}\textbackslash n

Updated: 2014-08-25

Converts the \langle roman numeral \rangle into the integer (base 10) representation and leaves this in the input stream. The \langle roman numeral \rangle may be in upper or lower case; if the numeral contains characters besides mdcclxvi or MDCLXVI then the resulting value is $-1$. This is the inverse function of \texttt{\textbackslash int\_to\_roman:n} and \texttt{\textbackslash int\_to\_Roman:n}.

\texttt{\textbackslash int\_from\_base:nn} \* \texttt{\textbackslash int\_from\_base:nn \{\textlangle\text{number}\}\} \{\textlangle\text{base}\}\}}\textbackslash n

Updated: 2014-08-25

Converts the \langle number \rangle expressed in \langle base \rangle into the appropriate value in base 10. The \langle number \rangle is first converted to a string, with no expansion. The \langle number \rangle should consist of digits and letters (either lower or upper case), plus optionally a leading sign. The maximum \langle base \rangle value is 36. This is the inverse function of \texttt{\textbackslash int\_to\_base:nn} and \texttt{\textbackslash int\_to\_Base:nn}.

\textbf{10 Random integers}

\texttt{\textbackslash int\_rand:nn} \* \texttt{\textbackslash int\_rand:nn \{\textlangle\text{intexpr}\}\} \{\textlangle\text{intexpr}\}\}}\textbackslash n

New: 2016-12-06
Updated: 2018-04-27

Evaluates the two \langle integer expressions \rangle and produces a pseudo-random number between the two (with bounds included). This is not available in older versions of \texttt{Xe\TeX}.

\texttt{\textbackslash int\_rand:n} \* \texttt{\textbackslash int\_rand:n \{\textlangle\text{intexpr}\}\}}\textbackslash n

New: 2018-05-05

Evaluates the \langle integer expression \rangle then produces a pseudo-random number between 1 and the \langle intexpr \rangle (included). This is not available in older versions of \texttt{Xe\TeX}.
11 Viewing integers

\texttt{int\_show:N} \texttt{(integer)}

Displays the value of the \texttt{integer} on the terminal.

\texttt{int\_show:n \{integer expression\}}

Displays the result of evaluating the \texttt{integer expression} on the terminal.

\texttt{int\_log:N} \texttt{integer}

Writes the value of the \texttt{integer} in the log file.

\texttt{int\_log:n \{integer expression\}}

Writes the result of evaluating the \texttt{integer expression} in the log file.

12 Constant integers

\texttt{c\_zero_int} \texttt{c\_one_int}

Integer values used with primitive tests and assignments: their self-terminating nature makes these more convenient and faster than literal numbers.

\texttt{c\_max_int}

The maximum value that can be stored as an integer.

\texttt{c\_max_register_int}

Maximum number of registers.

\texttt{c\_max_char_int}

Maximum character code completely supported by the engine.

13 Scratch integers

\texttt{l\_tmpa_int} \texttt{l\_tmpb_int}

Scratch integer for local assignment. These are never used by the kernel code, and so are safe for use with any \texttt{IMEX3}-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

\texttt{g\_tmpa_int} \texttt{g\_tmpb_int}

Scratch integer for global assignment. These are never used by the kernel code, and so are safe for use with any \texttt{IMEX3}-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.
13.1 Direct number expansion

\int_value:w * \int_value:w \langle integer \rangle
\langle integer \rangle \langle integer denotation \rangle \langle optional space \rangle

Expands the following tokens until an \langle integer \rangle is formed, and leaves a normalized form (no leading sign except for negative numbers, no leading digit 0 except for zero) in the input stream as category code 12 (other) characters. The \langle integer \rangle can consist of any number of signs (with intervening spaces) followed by

- an integer variable (in fact, any \TeX register except \texttt{\toks}) or
- explicit digits (or by \texttt{\langle octal digits \rangle} or \texttt{\langle hexadecimal digits \rangle} or \texttt{\langle character \rangle}).

In this last case expansion stops once a non-digit is found; if that is a space it is removed as in \texttt{f-expansion}, and so \texttt{\exp_stop_f:} may be employed as an end marker. Note that protected functions are expanded by this process.

This function requires exactly one expansion to produce a value, and so is suitable for use in cases where a number is required “directly”. In general, \texttt{\int_eval:n} is the preferred approach to generating numbers.

\TeXhacker\texttt{note}: This is the \TeX primitive \texttt{\number}.

14 Primitive conditionals

\if_int_compare:w * \if_int_compare:w \langle integer_1 \rangle \langle relation \rangle \langle integer_2 \rangle
\langle true code \rangle
\else:
\langle false code \rangle
\fi:

Compare two integers using \langle relation \rangle, which must be one of =, < or > with category code 12. The \texttt{\else:} branch is optional.

\TeXhacker\texttt{note}: These are both names for the \TeX primitive \texttt{\ifnum}.

\if_case:w * \if_case:w \langle integer \rangle \langle case_0 \rangle
\or: \langle case_1 \rangle
\or: \ldots
\else: \langle default \rangle
\fi:

Selects a case to execute based on the value of the \langle integer \rangle. The first case (\langle case_0 \rangle) is executed if \langle integer \rangle is 0, the second (\langle case_1 \rangle) if the \langle integer \rangle is 1, etc. The \langle integer \rangle may be a literal, a constant or an integer expression (\textit{e.g.} using \texttt{\int_eval:n}).

\TeXhacker\texttt{note}: These are the \TeX primitives \texttt{\ifcase} and \texttt{\or}. 

100
\if_int_odd:w \if_int_odd:w \tokens (tokens) \optional space (optional space) \true code (true code) \else: \true code (true code) \fi:

Expands \tokens until a non-numeric token or a space is found, and tests whether the resulting \integer is odd. If so, \true code is executed. The \else: branch is optional.

\LaTeXhackers note: This is the \LaTeX primitive \ifodd.
Part XII

The l3flag package: Expandable flags

Flags are the only data-type that can be modified in expansion-only contexts. This module is meant mostly for kernel use: in almost all cases, booleans or integers should be preferred to flags because they are very significantly faster.

A flag can hold any non-negative value, which we call its \langle height \rangle. In expansion-only contexts, a flag can only be “raised”: this increases the \langle height \rangle by 1. The \langle height \rangle can also be queried expandably. However, decreasing it, or setting it to zero requires non-expandable assignments.

Flag variables are always local. They are referenced by a \langle flag name \rangle such as str_missing. The \langle flag name \rangle is used as part of \use: constructions hence is expanded at point of use. It must expand to character tokens only, with no spaces.

A typical use case of flags would be to keep track of whether an exceptional condition has occurred during expandable processing, and produce a meaningful (non-expandable) message after the end of the expandable processing. This is exemplified by l3str-convert, which for performance reasons performs conversions of individual characters expandably and for readability reasons produces a single error message describing incorrect inputs that were encountered.

Flags should not be used without carefully considering the fact that raising a flag takes a time and memory proportional to its height. Flags should not be used unless unavoidable.

1 Setting up flags

\flag_new:n \{\langle flag name \rangle\}

Creates a new flag with a name given by \langle flag name \rangle, or raises an error if the name is already taken. The \langle flag name \rangle may not contain spaces. The declaration is global, but flags are always local variables. The \langle flag \rangle initially has zero height.

\flag_clear:n \{\langle flag name \rangle\}

The \langle flag \rangle's height is set to zero. The assignment is local.

\flag_clear_new:n \{\langle flag name \rangle\}

Ensures that the \langle flag \rangle exists globally by applying \flag_new:n if necessary, then applies \flag_clear:n, setting the height to zero locally.

\flag_show:n \{\langle flag name \rangle\}

Displays the \langle flag \rangle's height in the terminal.

\flag_log:n \{\langle flag name \rangle\}

Writes the \langle flag \rangle's height to the log file.
2 Expandable flag commands

`\flag_if_exist:n {⟨flag name⟩}`
This function returns `true` if the `⟨flag name⟩` references a flag that has been defined previously, and `false` otherwise.

`\flag_if_exist:nTF`  

`\flag_if_raised:n {⟨flag name⟩}`
This function returns `true` if the `⟨flag⟩` has non-zero height, and `false` if the `⟨flag⟩` has zero height.

`\flag_if_raised:nTF`  

`\flag_height:n {⟨flag name⟩}`
Expands to the height of the `⟨flag⟩` as an integer denotation.

`\flag_raise:n {⟨flag name⟩}`
The `⟨flag⟩`’s height is increased by 1 locally.
Part XIII

The l3prg package

Control structures

Conditional processing in \LaTeX\ has two forms of conditional flow processing based on these states. The first form is predicate functions that turn the returned state into a boolean \texttt{⟨true⟩} or \texttt{⟨false⟩}. For example, the function \texttt{\cs_if_free_p:N} checks whether the control sequence given as its argument is free and then returns the boolean \texttt{⟨true⟩} or \texttt{⟨false⟩} values to be used in testing with \texttt{\if\predicat:w} or in functions to be described below. The second form is the kind of functions choosing a particular argument from the input stream based on the result of the testing as in \texttt{\cs_if_free:NTF} which also takes one argument (the \texttt{N}) and then executes either \texttt{true} or \texttt{false} depending on the result.

\textbf{\TeX\ hackers note:} The arguments are executed after exiting the underlying \texttt{\if\ldots\fi:} structure.

1 Defining a set of conditional functions

\begin{verbatim}
\prg_new_conditional:Npnn \prg_new_conditional:Nnn \prg_new_protected_conditional:Npnn \prg_set_conditional:Npnn \prg_set_protected_conditional:Npnn
\prg_new_conditional:Nnpn \prg_new_conditional:Nnn \prg_new_protected_conditional:Nnn \prg_set_conditional:Nnpn \prg_set_protected_conditional:Nnn
\end{verbatim}

These functions create a family of conditionals using the same \texttt{⟨code⟩} to perform the test created. Those conditionals are expandable if \langle code \rangle is. The \texttt{new} versions check for existing definitions and perform assignments globally (\texttt{cf. \cs_new:Npn}) whereas the \texttt{set} versions do no check and perform assignments locally (\texttt{cf. \cs_set:Npn}). The conditionals created are dependent on the comma-separated list of \langle conditions \rangle, which should be one or more of \texttt{p, T, F and TF}.

\begin{verbatim}
\prg_new_protected_conditional:Nn \prg_new_protected_conditional:Nnn \prg_set_protected_conditional:Nn \prg_set_protected_conditional:Nnn
\end{verbatim}

These functions create a family of protected conditionals using the same \texttt{⟨code⟩} to perform the test created. The \langle code \rangle does not need to be expandable. The \texttt{new} version check for existing definitions and perform assignments globally (\texttt{cf. \cs_new:Npn}) whereas the \texttt{set} version do not (\texttt{cf. \cs_set:Npn}). The conditionals created are depended on the comma-separated list of \langle conditions \rangle, which should be one or more of \texttt{T, F and TF} (not \texttt{p}).

The conditionals are defined by \texttt{\prg_new_conditional:Nn} and friends as:
\(\text{name}_p:\langle\text{arg spec}\rangle\) — a predicate function which will supply either a logical \text{true} or logical \text{false}. This function is intended for use in cases where one or more logical tests are combined to lead to a final outcome. This function cannot be defined for \text{protected} conditionals.

\(\text{name}\):\langle\text{arg spec}\rangle T — a function with one more argument than the original \langle\text{arg spec}\rangle demands. The \langle\text{true branch}\rangle code in this additional argument will be left on the input stream only if the test is \text{true}.

\(\text{name}\):\langle\text{arg spec}\rangle F — a function with one more argument than the original \langle\text{arg spec}\rangle demands. The \langle\text{false branch}\rangle code in this additional argument will be left on the input stream only if the test is \text{false}.

\(\text{name}\):\langle\text{arg spec}\rangle TF — a function with two more argument than the original \langle\text{arg spec}\rangle demands. The \langle\text{true branch}\rangle code in the first additional argument will be left on the input stream if the test is \text{true}, while the \langle\text{false branch}\rangle code in the second argument will be left on the input stream if the test is \text{false}.

The \langle\text{code}\rangle of the test may use \langle\text{parameters}\rangle as specified by the second argument to \text{\prg_set_conditional:Npnn}: this should match the \langle\text{argument specification}\rangle but this is not enforced. The \text{Nnn} versions infer the number of arguments from the argument specification given (\text{cf.} \text{\cs_new:Nn}, \text{etc.}). Within the \langle\text{code}\rangle, the functions \text{\prg_return_true:} and \text{\prg_return_false:} are used to indicate the logical outcomes of the test.

An example can easily clarify matters here:

\begin{verbatim}
\prg_set_conditional:Npnn \foo_if_bar:NN #1#2 { p , T , TF }
{ \if_meaning:w \l_tmpa_tl #1 \prg_return_true: \else: \if_meaning:w \l_tmpa_tl #2 \prg_return_true: \else: \prg_return_false: \fi: \fi: }
\end{verbatim}

This defines the function \text{\foo_if_bar_p:NN}, \text{\foo_if_bar:NNTF} and \text{\foo_if_bar:NNT} but not \text{\foo_if_bar:NNF} (because \text{F} is missing from the \langle\text{conditions}\rangle list). The return statements take care of resolving the remaining \text{\else:} and \text{\fi:} before returning the state. There must be a return statement for each branch; failing to do so will result in erroneous output if that branch is executed.

\begin{verbatim}
\prg_new_eq_conditional:NNn \prg_new_eq_conditional:NNn \langle\text{conditions}\rangle
\prg_set_eq_conditional:NNn \langle\text{conditions}\rangle
\end{verbatim}

These functions copy a family of conditionals. The \text{new} version checks for existing definitions (\text{cf.} \text{\cs_new_eq:NN}) whereas the \text{set} version does not (\text{cf.} \text{\cs_set_eq:NN}). The conditionals copied are depended on the comma-separated list of \langle\text{conditions}\rangle, which should be one or more of \text{p}, \text{T}, \text{F} and \text{TF}.
These “return” functions define the logical state of a conditional statement. They appear within the code for a conditional function generated by \texttt{\prg_set_conditional:Npnn}, etc., to indicate when a true or false branch should be taken. While they may appear multiple times each within the code of such conditionals, the execution of the conditional must result in the expansion of one of these two functions exactly once.

The return functions trigger what is internally an \texttt{f}-expansion process to complete the evaluation of the conditional. Therefore, after \texttt{\prg_return_true:} or \texttt{\prg_return_false:} there must be no non-expandable material in the input stream for the remainder of the expansion of the conditional code. This includes other instances of either of these functions.

\begin{verbatim}
\prg_generate_conditional_variant:Nnn \prg_generate_conditional_variant:Nnn
\end{verbatim}

Defines argument-specifier variants of conditionals. This is equivalent to running \texttt{\cs_generate_variant:Nn \langle conditional \rangle \langle variant argument specifiers \rangle} on each \langle conditional \rangle described by the \langle condition specifiers \rangle. These base-form \langle conditionals \rangle are obtained from the \langle name \rangle and \langle arg spec \rangle as described for \texttt{\prg_new_conditional:Npnn}, and they should be defined.

\section{The boolean data type}

This section describes a boolean data type which is closely connected to conditional processing as sometimes you want to execute some code depending on the value of a switch (\textit{e.g.}, draft/final) and other times you perhaps want to use it as a predicate function in an \texttt{if predicate:w} test. The problem of the primitive \texttt{\if_false:} and \texttt{\if_true:} tokens is that it is not always safe to pass them around as they may interfere with scanning for termination of primitive conditional processing. Therefore, we employ two canonical booleans: \texttt{\c_true_bool} or \texttt{\c_false_bool}. Besides preventing problems as described above, it also allows us to implement a simple boolean parser supporting the logical operations \texttt{And}, \texttt{Or}, \texttt{Not}, \texttt{etc.} which can then be used on both the boolean type and predicate functions.

All conditional \texttt{\bool_} functions except assignments are expandable and expect the input to also be fully expandable (which generally means being constructed from predicate functions and booleans, possibly nested).

\textbf{\TeX{}hackers note}: The \texttt{\bool_} data type is not implemented using the \texttt{\iffalse}/\texttt{\iftrue} primitives, in contrast to \texttt{\newif}, \texttt{etc.}, in plain \TeX{}, \texttt{\pdfTeX} and so on. Programmers should not base use of \texttt{\bool_} switches on any particular expectation of the implementation.

\begin{verbatim}
\bool_new:N \bool_new:c
\end{verbatim}

Creates a new \langle boolean \rangle or raises an error if the name is already taken. The declaration is global. The \langle boolean \rangle is initially \texttt{false}.
\bool_const:Nn
\bool_const:cn
New: 2017-11-28

\bool_const:Nn \bool_const:cn
\langle boolean \rangle \{ \langle boolexpr \rangle \}
Creates a new constant \langle boolean \rangle or raises an error if the name is already taken. The value of the \langle boolean \rangle is set globally to the result of evaluating the \langle boolexpr \rangle.

\bool_set_false:N \bool_set_false:c
Sets \langle boolean \rangle logically false.

\bool_set_true:N \bool_set_true:c
Sets \langle boolean \rangle logically true.

\bool_set_eq:NN \bool_gset_eq: \langle boolean1 \rangle \langle boolean2 \rangle
Sets \langle boolean1 \rangle to the current value of \langle boolean2 \rangle.

\bool_set:Nn \bool_gset:N \langle boolean \rangle \{ \langle boolexpr \rangle \}
Evaluates the \langle boolean expression \rangle as described for \bool_if:nTF, and sets the \langle boolean \rangle variable to the logical truth of this evaluation.

\bool_if_p:N \bool_if_p:c \bool_if:NTF \bool_if:cTF
Tests the current truth of \langle boolean \rangle, and continues expansion based on this result.

\bool_show:N \bool_show:c
Displays the logical truth of the \langle boolean \rangle on the terminal.

\bool_show:n \bool_gset_eq: \langle boolean expression \rangle
Displays the logical truth of the \langle boolean expression \rangle on the terminal.

\bool_log:N \bool_log:c
Writes the logical truth of the \langle boolean \rangle in the log file.
\bool_log:n \{(boolean expression)\}

Writes the logical truth of the \textit{(boolean expression)} in the log file.

\bool_if_exist_p:N (boolean)
\bool_if_exist_p:c * 
\bool_if_exist:NTF (boolean) \{(true code)\} \{(false code)\}

Tests whether the \textit{(boolean)} is currently defined. This does not check that the \textit{(boolean)} really is a boolean variable.

\l_tmpa_bool
\l_tmpb_bool

A scratch boolean for local assignment. It is never used by the kernel code, and so is safe for use with any \LaTeX3-defined function. However, it may be overwritten by other non-kernel code and so should only be used for short-term storage.

\g_tmpa_bool
\g_tmpb_bool

A scratch boolean for global assignment. It is never used by the kernel code, and so is safe for use with any \LaTeX3-defined function. However, it may be overwritten by other non-kernel code and so should only be used for short-term storage.

\section{Boolean expressions}

As we have a boolean datatype and predicate functions returning boolean \textit{(true)} or \textit{(false)} values, it seems only fitting that we also provide a parser for \textit{(boolean expressions)}.

A boolean expression is an expression which given input in the form of predicate functions and boolean variables, return boolean \textit{(true)} or \textit{(false)}. It supports the logical operations And, Or and Not as the well-known infix operators \texttt{&&} and \texttt{||} and prefix \texttt{!} with their usual precedences (namely, \texttt{&&} binds more tightly than \texttt{||}). In addition to this, parentheses can be used to isolate sub-expressions. For example,

\begin{verbatim}
\int_compare_p:n { 1 = 1 } &&
  \int_compare_p:n { 2 = 3 } ||
\int_compare_p:n { 4 <= 4 } ||
\str_if_eq_p:nn { abc } { def }
\)
\end{verbatim}

is a valid boolean expression.

Contrarily to some other programming languages, the operators \texttt{&&} and \texttt{||} evaluate both operands in all cases, even when the first operand is enough to determine the result. This “eager” evaluation should be contrasted with the “lazy” evaluation of \texttt{\bool_lazy_} functions.

\texttt{\LaTeX3hac\b\k\ o\ n\ e\ s \textit{note:}} The eager evaluation of boolean expressions is unfortunately necessary in \LaTeX. Indeed, a lazy parser can get confused if \texttt{&&} or \texttt{||} or parentheses appear as (unbraced) arguments of some predicates. For instance, the innocuous-looking expression below would break (in a lazy parser) if \texttt{#1} were a closing parenthesis and \texttt{\l_tmpa_bool} were \texttt{true}.

\begin{verbatim}
( \l_tmpa_bool || \token_if_eq_meaning_p:NN X #1 )
\end{verbatim}
Minimal (lazy) evaluation can be obtained using the conditionals \texttt{\bool_lazy_all:nTF}, \texttt{\bool_lazy_and:nnTF}, \texttt{\bool_lazy_any:nTF}, or \texttt{\bool_lazy_or:nnTF}, which only evaluate their boolean expression arguments when they are needed to determine the resulting truth value. For example, when evaluating the boolean expression

\begin{verbatim}
\bool_lazy_and_p:nn
{  
  \bool_lazy_any_p:n
  { \int_compare_p:n { 2 = 3 } }
  { \int_compare_p:n { 4 <= 4 } }
  { \int_compare_p:n { 1 = \error } } \% skipped
}
{ ! \int_compare_p:n { 2 = 4 } }
\end{verbatim}

the line marked with \texttt{skipped} is not expanded because the result of \texttt{\bool_lazy_any_p:n} is known once the second boolean expression is found to be logically \texttt{true}. On the other hand, the last line is expanded because its logical value is needed to determine the result of \texttt{\bool_lazy_and_p:nn}.

\begin{verbatim}
\bool_if_p:n { ⟨boolean expression⟩ }
\bool_if:nTF { ⟨boolean expression⟩ } { ⟨true code⟩ } { ⟨false code⟩ }
\end{verbatim}

Tests the current truth of \texttt{⟨boolean expression⟩}, and continues expansion based on this result. The \texttt{⟨boolean expression⟩} should consist of a series of predicates or boolean variables with the logical relationship between these defined using \texttt{&&} (“And”), \texttt{||} (“Or”), \texttt{!} (“Not”) and parentheses. The logical \texttt{Not} applies to the next predicate or group.

\begin{verbatim}
\bool_lazy_all_p:n { {⟨boolexpr⟩1} {⟨boolexpr⟩2} ⋯ {⟨boolexpr⟩N} }
\bool_lazy_all:nTF { {⟨boolexpr⟩1} {⟨boolexpr⟩2} ⋯ {⟨boolexpr⟩N} } {⟨true code⟩} {⟨false code⟩}
\end{verbatim}

Implements the “And” operation on the \texttt{⟨boolean expressions⟩}, hence is \texttt{true} if all of them are \texttt{true} and \texttt{false} if any of them is \texttt{false}. Contrarily to the infix operator \texttt{&&}, only the \texttt{⟨boolean expressions⟩} which are needed to determine the result of \texttt{\bool_lazy_all:nTF} are evaluated. See also \texttt{\bool_lazy_and:nnTF} when there are only two \texttt{⟨boolean expressions⟩}.

\begin{verbatim}
\bool_lazy_and_p:nn { {⟨boolexpr⟩1} {⟨boolexpr⟩2} }
\bool_lazy_and:nnTF { {⟨boolexpr⟩1} {⟨boolexpr⟩2} } {⟨true code⟩} {⟨false code⟩}
\end{verbatim}

Implements the “And” operation between two boolean expressions, hence is \texttt{true} if both are \texttt{true}. Contrarily to the infix operator \texttt{&}, the \texttt{⟨boolexpr⟩2} is only evaluated if it is needed to determine the result of \texttt{\bool_lazy_and:nnTF}. See also \texttt{\bool_lazy_all:nTF} when there are more than two \texttt{⟨boolean expressions⟩}.
4 Logical loops

Loops using either boolean expressions or stored boolean values.

\bool_lazy_or_p:n \* \bool_lazy_or:p:nn \*
\bool_lazy_or:n \* \bool_lazy_or:nn \* 
\bool_lazy_or:nnTF \* 
\bool_lazy_any_p:n \* \bool_lazy_any:n \* \bool_lazy_any:p:n \* 
\bool_lazy_any:nTF \* 
\bool_until_do:cn \* \bool_until_do:Nn \* 
\bool_until_do:nTF \* 
\bool_do_while:cn \* \bool_do_while:Nn \* 
\bool_do_while:nTF \* 
\bool_do_until:cn \* \bool_do_until:Nn \* 
\bool_do_until:nTF \* 
\bool_xor:p:nn \* \bool_xor:nn \* 
\bool_xor:nTF \* \bool_xor:n:nn \* 
\bool_not_p:n \* \bool_not:n \* 
\bool_not:p:n \* 
\bool_xor:nTF \* \bool_xor:p:nn \* 
\bool_until_do:n:nn \* \bool_until_do:nTF \* 
\bool_do_until:n:nn \* \bool_do_until:nTF \* 
\bool_do_while:n:nn \* \bool_do_while:nTF \* 
\bool_do_while:n:nn \* \bool_do_while:nTF \* 
\bool_do_until:n:nn \* \bool_do_until:nTF \* 
\bool_do_while:n:nn \* \bool_do_while:nTF \* 

Implements the “Or” operation on the \langle boolean expressions \rangle, hence is \texttt{true} if any of them is \texttt{true} and \texttt{false} if all of them are \texttt{false}. Contrarily to the infix operator \langle | | \rangle, only the \langle boolean expressions \rangle which are needed to determine the result of \bool_lazy_-any:nTF are evaluated. See also \bool_lazy_or:nnTF when there are only two \langle boolean expressions \rangle.

Implements the “Or” operation between two boolean expressions, hence is \texttt{true} if either one is \texttt{true}. Contrarily to the infix operator \langle | | \rangle, the \langle boolean \rangle is only evaluated if it is needed to determine the result of \bool_lazy_or:nTF. See also \bool_lazy_any:nTF when there are more than two \langle boolean expressions \rangle.

Function version of \langle !(\langle boolean expression \rangle) \rangle within a boolean expression.

Implements an “exclusive or” operation between two boolean expressions. There is no infix operation for this logical operation.

Places the \langle code \rangle in the input stream for \LaTeX{} to process, and then checks the logical value of the \langle boolean \rangle. If it is \texttt{false} then the \langle code \rangle is inserted into the input stream again and the process loops until the \langle boolean \rangle is \texttt{true}.

Places the \langle code \rangle in the input stream for \LaTeX{} to process, and then checks the logical value of the \langle boolean \rangle. If it is \texttt{true} then the \langle code \rangle is inserted into the input stream again and the process loops until the \langle boolean \rangle is \texttt{false}.

This function firsts checks the logical value of the \langle boolean \rangle. If it is \texttt{false} the \langle code \rangle is placed in the input stream and expanded. After the completion of the \langle code \rangle the truth of the \langle boolean \rangle is re-evaluated. The process then loops until the \langle boolean \rangle is \texttt{true}.

This function firsts checks the logical value of the \langle boolean \rangle. If it is \texttt{true} the \langle code \rangle is placed in the input stream and expanded. After the completion of the \langle code \rangle the truth of the \langle boolean \rangle is re-evaluated. The process then loops until the \langle boolean \rangle is \texttt{false}.
\bool_do_until:nn \bool_do_until:nn \\{boolean expression\} \{\langle code\rangle\} \\{\langle code\rangle\} \\{\langle code\rangle\}
Places the \langle code\rangle in the input stream for \TeX to process, and then checks the logical value of the \langle boolean expression\rangle as described for \bool_if:nTF. If it is false then the \langle code\rangle is inserted into the input stream again and the process loops until the \langle boolean expression\rangle evaluates to true.

\bool_do_while:nn \bool_do_while:nn \\{boolean expression\} \{\langle code\rangle\} \\{\langle code\rangle\} \\{\langle code\rangle\}
Places the \langle code\rangle in the input stream for \TeX to process, and then checks the logical value of the \langle boolean expression\rangle as described for \bool_if:nTF. If it is true then the \langle code\rangle is inserted into the input stream again and the process loops until the \langle boolean expression\rangle evaluates to false.

\bool_until_do:nn \bool_until_do:nn \\{boolean expression\} \{\langle code\rangle\} \\{\langle code\rangle\} \\{\langle code\rangle\}
This function firsts checks the logical value of the \langle boolean expression\rangle (as described for \bool_if:nTF). If it is false the \langle code\rangle is placed in the input stream and expanded. After the completion of the \langle code\rangle the truth of the \langle boolean expression\rangle is re-evaluated. The process then loops until the \langle boolean expression\rangle is true.

\bool_while_do:nn \bool_while_do:nn \\{boolean expression\} \{\langle code\rangle\} \\{\langle code\rangle\} \\{\langle code\rangle\}
This function firsts checks the logical value of the \langle boolean expression\rangle (as described for \bool_if:nTF). If it is true the \langle code\rangle is placed in the input stream and expanded. After the completion of the \langle code\rangle the truth of the \langle boolean expression\rangle is re-evaluated. The process then loops until the \langle boolean expression\rangle is false.

5 Producing multiple copies
\prg_replicate:nn \prg_replicate:nn \\{integer expression\} \\{\langle tokens\rangle\} \\{\langle tokens\rangle\}
Evaluates the \langle integer expression\rangle (which should be zero or positive) and creates the resulting number of copies of the \langle tokens\rangle. The function is both expandable and safe for nesting. It yields its result after two expansion steps.

6 Detecting \TeX’s mode
\mode_if_horizontal_p: \mode_if_horizontal_p: \\{true code\} \\{\langle code\rangle\} \\{\langle code\rangle\}
\\{false code\} \\{\langle code\rangle\}
Detects if \TeX is currently in horizontal mode.

\mode_if_inner_p: \mode_if_inner_p: \\{true code\} \\{\langle code\rangle\} \\{\langle code\rangle\}
\\{false code\} \\{\langle code\rangle\}
Detects if \TeX is currently in inner mode.

\mode_if_math_p: \mode_if_math_p: \\{true code\} \\{\langle code\rangle\} \\{\langle code\rangle\}
\\{false code\} \\{\langle code\rangle\}
Detects if \TeX is currently in maths mode.

111
Detects if \TeX{} is currently in vertical mode.

## 7  Primitive conditionals

\begin{itemize}
  \item \texttt{\if_predicate:w} \langle predicate \rangle \langle true code \rangle \\else: \langle false code \rangle \\fi:
  \end{itemize}

This function takes a predicate function and branches according to the result. (In practice this function would also accept a single boolean variable in place of the \langle predicate \rangle but to make the coding clearer this should be done through \texttt{\if_bool:N}.)

\begin{itemize}
  \item \texttt{\if_bool:N} \langle boolean \rangle \langle true code \rangle \\else: \langle false code \rangle \\fi:
  \end{itemize}

This function takes a boolean variable and branches according to the result.

## 8  Nestable recursions and mappings

There are a number of places where recursion or mapping constructs are used in \texttt{expl3}. At a low-level, these typically require insertion of tokens at the end of the content to allow “clean up”. To support such mappings in a nestable form, the following functions are provided.

\begin{itemize}
  \item \texttt{\prg_break_point:Nn} \langle type \rangle _{\text{map_break:}} \{ \langle code \rangle \}
  \end{itemize}

Used to mark the end of a recursion or mapping: the functions \texttt{\langle type \rangle _{\text{map_break:}} \texttt{\texttt{\prg_map_break:Nn}} \langle type \rangle _{\text{map_break:}}:} and \texttt{\langle type \rangle _{\text{map_break:n}} use this to break out of the loop (see \texttt{\prg_map_break:Nn for how to set these up). After the loop ends, the \langle code \rangle is inserted into the input stream. This occurs even if the break functions are not applied: \texttt{\prg_break_point:Nn is functionally-equivalent in these cases to \texttt{\use_ii:nn}.}

\begin{itemize}
  \item \texttt{\prg_map_break:Nn} \langle type \rangle _{\text{map_break:}} \{ \langle user code \rangle \}
  \end{itemize}

\begin{itemize}
  \item \texttt{\prg_map_break:Nn} \langle type \rangle _{\text{map_break:}} \{ \langle ending code \rangle \}
  \end{itemize}

Breaks a recursion in mapping contexts, inserting in the input stream the \langle user code \rangle after the \langle ending code \rangle for the loop. The function breaks loops, inserting their \langle ending code \rangle, until reaching a loop with the same \langle type \rangle as its first argument. This \texttt{\langle type \rangle _{\text{map_break:}} argument must be defined; it is simply used as a recognizable marker for the \langle type \rangle.

For types with mappings defined in the kernel, \texttt{\langle type \rangle _{\text{map_break:}} and \langle type \rangle _{\text{map_break:n}} are defined as \texttt{\prg_map_break:Nn} \langle type \rangle _{\text{map_break:}} \{ \} and the same with \{ \} omitted.

### 8.1  Simple mappings

In addition to the more complex mappings above, non-nestable mappings are used in a number of locations and support is provided for these.
This copy of \texttt{\prg_do_nothing}: is used to mark the end of a fast short-term recursion: the function \texttt{\prg_break:n} uses this to break out of the loop.

\begin{tikzpicture}
\node[anchor=east] at (0,0) {\texttt{\prg_break_point:}};
\end{tikzpicture}

\texttt{\prg_break: \prg_break:n \prg_break:} \texttt{(code)} \ldots \texttt{\prg_break_point:}

Breaks a recursion which has no \textit{(ending code)} and which is not a user-breakable mapping (see for instance \texttt{\prop_get:Nn}), and inserts the \texttt{(code)} in the input stream.

\section{Internal programming functions}

\begin{tikzpicture}
\node[anchor=east] at (0,0) {\texttt{\group_align_safe_begin:}};
\end{tikzpicture}
\begin{tikzpicture}
\node[anchor=east] at (0,0) {\texttt{\group_align_safe_end:}};
\end{tikzpicture}

These functions are used to enclose material in a \TeX{} alignment environment within a specially-constructed group. This group is designed in such a way that it does not add brace groups to the output but does act as a group for the \texttt{&} token inside \texttt{\halign}. This is necessary to allow grabbing of tokens for testing purposes, as \TeX{} uses group level to determine the effect of alignment tokens. Without the special grouping, the use of a function such as \texttt{\peek_after:Nw} would result in a forbidden comparison of the internal \texttt{\endtemplate} token, yielding a fatal error. Each \texttt{\group_align_safe_begin:} must be matched by a \texttt{\group_align_safe_end:}; although this does not have to occur within the same function.
Part XIV
The l3sys package: System/runtime functions

1 The name of the job

\texttt{\textbackslash c\_sys\_jobname\_str}

Constant that gets the “job name” assigned when \TeX\ starts.

\textbf{\TeX\ hackers note:} This copies the contents of the primitive \texttt{\jobname}. For technical reasons, the string here is not of the same internal form as other, but may be manipulated using normal string functions.

2 Date and time

\texttt{\textbackslash c\_sys\_minute\_int}
\texttt{\textbackslash c\_sys\_hour\_int}
\texttt{\textbackslash c\_sys\_day\_int}
\texttt{\textbackslash c\_sys\_month\_int}
\texttt{\textbackslash c\_sys\_year\_int}

The date and time at which the current job was started: these are all reported as integers.

\textbf{\TeX\ hackers note:} Whilst the underlying primitives can be altered by the user, this interface to the time and date is intended to be the “real” values.

3 Engine

\texttt{\textbackslash sys\_if\_engine\_luatex\_p: \ast}
\texttt{\textbackslash sys\_if\_engine\_luatex: \texttt{\textbackslash TF: \ast}}
\texttt{\textbackslash sys\_if\_engine\_pdftex\_p: \ast}
\texttt{\textbackslash sys\_if\_engine\_pdftex: \texttt{\textbackslash TF: \ast}}
\texttt{\textbackslash sys\_if\_engine\_ptex\_p: \ast}
\texttt{\textbackslash sys\_if\_engine\_ptex: \texttt{\textbackslash TF: \ast}}
\texttt{\textbackslash sys\_if\_engine\_uptex\_p: \ast}
\texttt{\textbackslash sys\_if\_engine\_uptex: \texttt{\textbackslash TF: \ast}}
\texttt{\textbackslash sys\_if\_engine\_xetex\_p: \ast}
\texttt{\textbackslash sys\_if\_engine\_xetex: \texttt{\textbackslash TF: \ast}}

\texttt{\textbackslash sys\_if\_engine\_pdftex: \texttt{\textbackslash TF: \langle true code\rangle \{false code\}}} \langle false code\rangle

Conditionals which allow engine-specific code to be used. The names follow naturally from those of the engine binaries: note that the (u)ptex tests are for \TeX and \upTeX as expl3 requires the \TeX\ extensions. Each conditional is true for \textit{exactly one} supported engine. In particular, \texttt{\textbackslash sys\_if\_engine\_ptex\_p:} is true for \TeX\ but false for \upTeX.

\texttt{\textbackslash c\_sys\_engine\_str}

The current engine given as a lower case string: one of \texttt{luatex, pdftex, ptx, uptex or xetex}.

114
4 Output format

\sys_if_output_dvi_p: * \sys_if_output_dvi:TF {(true code)} {(false code)}
\sys_if_output_pdf_p: * \sys_if_output_pdf:TF *

Conditionals which give the current output mode the \TeX{} run is operating in. This is always one of two outcomes, DVI mode or PDF mode. The two sets of conditionals are thus complementary and are both provided to allow the programmer to emphasise the most appropriate case.

The current output mode given as a lower case string: one of dvi or pdf.

5 Platform

\sys_if_platform_unix_p: * \sys_if_platform_unix:TF {(true code)} {(false code)}
\sys_if_platform_windows_p: * \sys_if_platform_windows:TF *

Conditionals which allow platform-specific code to be used. The names follow the Lua os.type() function, i.e. all Unix-like systems are unix (including Linux and MacOS).

The current platform given as a lower case string: one of unix, windows or unknown.

6 Random numbers

\sys_rand_seed: *

Expands to the current value of the engine’s random seed, a non-negative integer. In engines without random number support this expands to 0.

\sys_gset_rand_seed:n \{intexpr\}

Globally sets the seed for the engine’s pseudo-random number generator to the \emph{integer expression}. This random seed affects all \ldots_rand functions (such as \int_rand:nn or \clist_rand_item:n) as well as other packages relying on the engine’s random number generator. In engines without random number support this produces an error.

\textbf{\TeX{}hackers note:} While a 32-bit (signed) integer can be given as a seed, only the absolute value is used and any number beyond \(2^{31}\) is divided by an appropriate power of 2. We recommend using an integer in \([0, 2^{32} − 1]\).
7 Access to the shell

\sys_get_shell:nnN \sys_get_shell:nnNTF

New: 2019-09-20

Defines \( tl \) to the text returned by the \( \text{shell command} \). The \( \text{shell command} \) is converted to a string using \( \text{tl_to_str:n} \). Category codes may need to be set appropriately via the \( \text{setup} \) argument, which is run just before running the \( \text{shell command} \) (in a group). If shell escape is disabled, the \( tl \) will be set to \q_no_value in the non-branching version. Note that quote characters (" cannot be used inside the \( \text{shell command} \). The \sys_get_shell:nnNTF conditional returns true if the shell is available and no quote is detected, and false otherwise.

\c_sys_shell_escape_int

New: 2017-05-27

This variable exposes the internal triple of the shell escape status. The possible values are:

- 0 Shell escape is disabled
- 1 Unrestricted shell escape is enabled
- 2 Restricted shell escape is enabled

\sys_if_shell_p: \sys_if_shell:TF

New: 2017-05-27

Performs a check for whether shell escape is enabled. This returns true if either of restricted or unrestricted shell escape is enabled.

\sys_if_shell_unrestricted_p: \sys_if_shell_unrestricted:TF

New: 2017-05-27

Performs a check for whether unrestricted shell escape is enabled.

\sys_if_shell_restricted_p: \sys_if_shell_restricted:TF

New: 2017-05-27

Performs a check for whether restricted shell escape is enabled. This returns false if unrestricted shell escape is enabled. Unrestricted shell escape is not considered a superset of restricted shell escape in this case. To find whether any shell escape is enabled use \sys_if_shell:.

\sys_shell_now:n \sys_shell_now:x

New: 2017-05-27

Execute \( \langle \text{tokens} \rangle \) through shell escape immediately.

\sys_shell_shipout:n \sys_shell_shipout:x

New: 2017-05-27

Execute \( \langle \text{tokens} \rangle \) through shell escape at shipout.
7.1 Loading configuration data

\sys_load_backend:n \{(backend)\}

Loads the additional configuration file needed for backend support. If the \(\texttt{backend}\) is empty, the standard backend for the engine in use will be loaded. This command may only be used once.

\c_sys_backend_str

Set to the name of the backend in use by \sys_load_backend:n when issued.

\sys_load_debug:
\sys_load_deprecation:

Load the additional configuration files for debugging support and rolling back deprecations, respectively.

7.2 Final settings

\sys_finalise:

Finalises all system-dependent functionality: required before loading a backend.
Part XV

The \texttt{l3clist} package

Comma separated lists

Comma lists contain ordered data where items can be added to the left or right end of the list. This data type allows basic list manipulations such as adding/removing items, applying a function to every item, removing duplicate items, extracting a given item, using the comma list with specified separators, and so on. Sequences (defined in \texttt{l3seq}) are safer, faster, and provide more features, so they should often be preferred to comma lists. Comma lists are mostly useful when interfacing with \LaTeX\ or other code that expects or provides comma list data.

Several items can be added at once. To ease input of comma lists from data provided by a user outside an \texttt{\ExplSyntaxOn...\ExplSyntaxOff} block, spaces are removed from both sides of each comma-delimited argument upon input. Blank arguments are ignored, to allow for trailing commas or repeated commas (which may otherwise arise when concatenating comma lists “by hand”). In addition, a set of braces is removed if the result of space-trimming is braced: this allows the storage of any item in a comma list. For instance,

\begin{verbatim}
\clist_new:N \l_my_clist
\clist_put_left:Nn \l_my_clist { -a- , -{b}- , c\-d }
\clist_put_right:Nn \l_my_clist { -{e} , , {f} , }
\end{verbatim}

results in \texttt{l_my_clist} containing \texttt{a,b,c\-d,e-} and \texttt{\{f\}} namely the five items \texttt{a, b, c\-d, e-} and \texttt{\{f\}}. Comma lists normally do not contain empty items so the following gives an empty comma list:

\begin{verbatim}
\clist_clear_new:N \l_my_clist
\clist_put_right:Nn \l_my_clist { , , }
\clist_if_empty:NTF \l_my_clist { true } { false }
\end{verbatim}

and it leaves true in the input stream. To include an “unsafe” item (empty, or one that contains a comma, or starts or ends with a space, or is a single brace group), surround it with braces.

Almost all operations on comma lists are noticeably slower than those on sequences so converting the data to sequences using \texttt{\seq_set_from_clist:Nn} (see \texttt{l3seq}) may be advisable if speed is important. The exception is that \texttt{\clist_if_in:NnTF} and \texttt{\clist_remove_duplicates:N} may be faster than their sequence analogues for large lists. However, these functions work slowly for “unsafe” items that must be braced, and may produce errors when their argument contains {,} or # (assuming the usual \TeX\ category codes apply). The sequence data type should thus certainly be preferred to comma lists to store such items.

1 Creating and initialising comma lists

\begin{verbatim}
\clist_new:N \clist_new:c
\end{verbatim}

\begin{verbatim}
\clist_new:N \l_my_clist
\end{verbatim}

\begin{verbatim}
\clist_new:N \clist_new:c
\end{verbatim}

Creates a new \texttt{(comma list)} or raises an error if the name is already taken. The declaration is global. The \texttt{(comma list)} initially contains no items.

118
\clist_const:Nn \clist_const:(N|cn|cx) \clist_const: \clist {\langle comma list\rangle} 

New: 2014-07-05

\clist_clear:N \clist_gclear:N \clist_clear:c \clist_gclear:c
\clist_clear: \langle comma list\rangle
Clears all items from the \langle comma list\rangle.

\clist_clear_new:N \clist_clear_new:c \clist_gclear_new:N \clist_gclear_new:c
\clist_clear_new: \langle comma list\rangle
Ensures that the \langle comma list\rangle exists globally by applying \clist_new:N if necessary, then applies \clist_(g)clear:N to leave the list empty.

\clist_set_eq:NN \clist_set_eq:(cN|Nc|cc)
\clist_gset_eq:NN \clist_gset_eq:(cN|Nc|cc)
Sets the content of \langle comma list\rangle 1 equal to that of \langle comma list\rangle 2.

\clist_set_from_seq:NN \clist_set_from_seq:(cN|Nc|cc)
\clist_gset_from_seq:NN \clist_gset_from_seq:(cN|Nc|cc)

New: 2014-07-17

Converts the data in the \langle sequence\rangle into a \langle comma list\rangle: the original \langle sequence\rangle is unchanged. Items which contain either spaces or commas are surrounded by braces.

\clist_concat:NNN \clist_concat:ccc \clist_gconcat:NNN \clist_gconcat:ccc
\clist_concat: \langle comma list\rangle \langle comma list\rangle \langle comma list\rangle
Concatenates the content of \langle comma list\rangle 2 and \langle comma list\rangle 3 together and saves the result in \langle comma list\rangle 1. The items in \langle comma list\rangle 2 are placed at the left side of the new comma list.

\clist_if_exist_p:N \clist_if_exist:p: \clist_if_exist:c \clist_if_exist:N \clist_if_exist:c
\clist_if_exist:p:N \clist_if_exist:NTF \clist_if_exist:cTF \clist_if_exist: \langle comma list\rangle
Tests whether the \langle comma list\rangle is currently defined. This does not check that the \langle comma list\rangle really is a comma list.
2 Adding data to comma lists

\clist_set:Nn \clist_set:Nn \clist_gset:Nn \clist_set: \clist_gset:

\clist_gput_left:Nn \clist_gput_left:Nn \clist_gput_right:Nn \clist_gput_right:Nn

Updated: 2011-09-05

Sets \langle comma list \rangle to contain the \langle items \rangle, removing any previous content from the variable. Blank items are omitted, spaces are removed from both sides of each item, then a set of braces is removed if the resulting space-trimmed item is braced. To store some \langle tokens \rangle as a single \langle item \rangle even if the \langle tokens \rangle contain commas or spaces, add a set of braces: \clist_set:Nn \langle comma list \rangle \{ \langle tokens \rangle \} .

\clist_put_left:Nn \clist_put_left:Nn \clist_gput_left:Nn \clist_gput_left:Nn

Updated: 2011-09-05

Appends the \langle items \rangle to the left of the \langle comma list \rangle. Blank items are omitted, spaces are removed from both sides of each item, then a set of braces is removed if the resulting space-trimmed item is braced. To append some \langle tokens \rangle as a single \langle item \rangle even if the \langle tokens \rangle contain commas or spaces, add a set of braces: \clist_put_left:Nn \langle comma list \rangle \{ \langle tokens \rangle \} .

\clist_put_right:Nn \clist_put_right:Nn \clist_gput_right:Nn \clist_gput_right:Nn

Updated: 2011-09-05

Appends the \langle items \rangle to the right of the \langle comma list \rangle. Blank items are omitted, spaces are removed from both sides of each item, then a set of braces is removed if the resulting space-trimmed item is braced. To append some \langle tokens \rangle as a single \langle item \rangle even if the \langle tokens \rangle contain commas or spaces, add a set of braces: \clist_put_right:Nn \langle comma list \rangle \{ \langle tokens \rangle \} .

3 Modifying comma lists

While comma lists are normally used as ordered lists, it may be necessary to modify the content. The functions here may be used to update comma lists, while retaining the order of the unaffected entries.

120
\clist_remove_duplicates:N ⟨comma list⟩
\clist_gremove_duplicates:N
Removes duplicate items from the ⟨comma list⟩, leaving the left most copy of each item in the ⟨comma list⟩. The ⟨item⟩ comparison takes place on a token basis, as for \tl_if_eq:nn(TF).

\TeXhackers note: This function iterates through every item in the ⟨comma list⟩ and does a comparison with the ⟨items⟩ already checked. It is therefore relatively slow with large comma lists. Furthermore, it may fail if any of the items in the ⟨comma list⟩ contains ⟨,⟩, or ⟨#⟩ (assuming the usual \TeX category codes apply).

\clist_remove_all:Nn ⟨comma list⟩ {⟨item⟩}
\clist_gremove_all:Nn
Removes every occurrence of ⟨item⟩ from the ⟨comma list⟩. The ⟨item⟩ comparison takes place on a token basis, as for \tl_if_eq:nn(TF).

\TeXhackers note: The function may fail if the ⟨item⟩ contains ⟨,⟩, or ⟨#⟩ (assuming the usual \TeX category codes apply).

\clist_reverse:N ⟨comma list⟩
\clist_greverse:N
Reverses the order of items stored in the ⟨comma list⟩.

\clist_reverse:n {⟨comma list⟩}
Leaves the items in the ⟨comma list⟩ in the input stream in reverse order. Contrarily to other what is done for other n-type ⟨comma list⟩ arguments, braces and spaces are preserved by this process.

\TeXhackers note: The result is returned within \unexpanded, which means that the comma list does not expand further when appearing in an x-type or e-type argument expansion.

\clist_sort:Nn ⟨clist var⟩ {⟨comparison code⟩}
\clist_gsort:Nn
Sorts the items in the ⟨clist var⟩ according to the ⟨comparison code⟩, and assigns the result to ⟨clist var⟩. The details of sorting comparison are described in Section 1.
4 Comma list conditionals

\clist_if_empty_p:N \clist_if_empty_p:N (comma list)
\clist_if_empty_p:c \clist_if_empty_p:N (comma list) \{\langle true code\rangle\} \{\langle false code\rangle\}
Tests if the \langle comma list\rangle is empty (containing no items).

\clist_if_empty:n \clist_if_empty:n \{\langle comma list\rangle\}
\clist_if_empty:nTF \{\langle comma list\rangle\} \{\langle true code\rangle\} \{\langle false code\rangle\}
Tests if the \langle comma list\rangle is empty (containing no items). The rules for space trimming are as for other n-type comma-list functions, hence the comma list {~,~,,~} (without outer braces) is empty, while {~,{},} (without outer braces) contains one element, which happens to be empty: the comma-list is not empty.

\clist_if_in:NnTF \langle comma list\rangle \{\langle item\rangle\} \{\langle true code\rangle\} \{\langle false code\rangle\}
\clist_if_in:N \langle comma list\rangle \{\langle item\rangle\} \{\langle true code\rangle\} \{\langle false code\rangle\}
\clist_if_in:nn \langle comma list\rangle \{\langle item\rangle\} \{\langle true code\rangle\} \{\langle false code\rangle\}
Tests if the \langle item\rangle is present in the \langle comma list\rangle. In the case of an n-type \langle comma list\rangle, the usual rules of space trimming and brace stripping apply. Hence,
\clist_if_in:nnTF { a , {b}/uni2423{}, /uni2423c, } { b } \{true\} \{false\}
yields true.

\TeXhackers note: The function may fail if the \langle item\rangle contains \{,\}, or \# (assuming the usual \TeX category codes apply).

5 Mapping to comma lists

The functions described in this section apply a specified function to each item of a comma list. All mappings are done at the current group level, i.e. any local assignments made by the \langle function\rangle or \langle code\rangle discussed below remain in effect after the loop.

When the comma list is given explicitly, as an n-type argument, spaces are trimmed around each item. If the result of trimming spaces is empty, the item is ignored. Otherwise, if the item is surrounded by braces, one set is removed, and the result is passed to the mapped function. Thus, if the comma list that is being mapped is \{a_{\cup\cup}\{\langle b\rangle\}_{\cup\cup}\{\langle c\rangle\}\}, then the arguments passed to the mapped function are ‘a’, ‘\langle b\rangle’, an empty argument, and ‘c’.

When the comma list is given as an N-type argument, spaces have already been trimmed on input, and items are simply stripped of one set of braces if any. This case is more efficient than using n-type comma lists.

\clist_map_function:NN \clist_map_function:CN \clist_map_function:nN
\clist_map_function:NN \langle comma list\rangle \langle function\rangle
\clist_map_function:NN \langle comma list\rangle \langle function\rangle
Applyes \langle function\rangle to every \langle item\rangle stored in the \langle comma list\rangle. The \langle function\rangle receives one argument for each iteration. The \langle items\rangle are returned from left to right. The function \clist_map_inline:Nn is in general more efficient than \clist_map_function:NN.
\clist_map_inline:Nn \clist_map_inline:cn \clist_map_inline:nn
Applies \textit{inline function} to every \textit{item} stored within the \textit{comma list}. The \textit{inline function} should consist of code which receives the \textit{item} as \#1. The \textit{items} are returned from left to right.

\clist_map_variable:NNn \clist_map_variable:cn \clist_map_variable:nn
Stores each \textit{item} of the \textit{comma list} in turn in the (token list) \textit{variable} and applies the \textit{code}. The \textit{code} will usually make use of the \textit{variable}, but this is not enforced. The assignments to the \textit{variable} are local. Its value after the loop is the last \textit{item} in the \textit{comma list}, or its original value if there were no \textit{item}. The \textit{items} are returned from left to right.

\clist_map_break:
Used to terminate a \texttt{\clist_map...} function before all entries in the \textit{comma list} have been processed. This normally takes place within a conditional statement, for example
\begin{verbatim}
\clist_map_inline:Nn \l_my_clist
  { \str_if_eq:nnTF { #1 } { bingo } { \clist_map_break: }
    { % Do something useful
  }
\end{verbatim}
Use outside of a \texttt{\clist_map...} scenario leads to low level \TeX{} errors.

\textbf{\TeX{}hackers note:} When the mapping is broken, additional tokens may be inserted before further items are taken from the input stream. This depends on the design of the mapping function.
\clist_map_break:n \clist_map_break:n {⟨code⟩}  

Used to terminate a \clist_map_... function before all entries in the ⟨comma list⟩ have been processed, inserting the ⟨code⟩ after the mapping has ended. This normally takes place within a conditional statement, for example

\clist_map_inline:Nn \l_my_clist  
{\str_if_eq:nnTF { #1 } { bingo } { \clist_map_break:n { ⟨code⟩ } }  
{ % Do something useful  
}  
}

Use outside of a \clist_map... scenario leads to low level \TeX errors.

\TeXhackers note: When the mapping is broken, additional tokens may be inserted before the ⟨code⟩ is inserted into the input stream. This depends on the design of the mapping function.

\clist_count:N \clist_count:N ⟨comma list⟩  
\clist_count:c \clist_count:n

Leaves the number of items in the ⟨comma list⟩ in the input stream as an ⟨integer denotation⟩. The total number of items in a ⟨comma list⟩ includes those which are duplicates, i.e. every item in a ⟨comma list⟩ is counted.

6 Using the content of comma lists directly

\clist_use:Nnnn \clist_use:cn

Places the contents of the ⟨clist var⟩ in the input stream, with the appropriate ⟨separator⟩ between the items. Namely, if the comma list has more than two items, the ⟨separator between more than two⟩ is placed between each pair of items except the last, for which the ⟨separator between final two⟩ is used. If the comma list has exactly two items, then they are placed in the input stream separated by the ⟨separator between two⟩. If the comma list has a single item, it is placed in the input stream, and a comma list with no items produces no output. An error is raised if the variable does not exist or if it is invalid.

For example,

\clist_set:Nn \l_tmpa_clist { a , b , , c , {de} , f }  
\clist_use:Nnnn \l_tmpa_clist { ~and~ } { ,~ } { ,~and~ }

inserts “a, b, c, de, and f” in the input stream. The first separator argument is not used in this case because the comma list has more than 2 items.

\TeXhackers note: The result is returned within the \unexpanded primitive (\exp_not:n), which means that the ⟨items⟩ do not expand further when appearing in an x-type argument expansion.
Placing the contents of the \clist var in the input stream, with the \sep between the items. If the comma list has a single item, it is placed in the input stream, and a comma list with no items produces no output. An error is raised if the variable does not exist or if it is invalid.

For example,

\begin{verbatim}
\clist_set:Nn \l_tmpa_clist { a , b , , c , {de} , f }
\clist_use:Nn \l_tmpa_clist { ~and~ }
\end{verbatim}

inserts “a and b and c and de and f” in the input stream.

\textbf{\TeXhackers note:} The result is returned within the \texttt{\unexpanded} primitive \texttt{\exp_not:n}, which means that the \texttt{\items} do not expand further when appearing in an \texttt{x}-type argument expansion.

7 Comma lists as stacks

Comma lists can be used as stacks, where data is pushed to and popped from the top of the comma list. (The left of a comma list is the top, for performance reasons.) The stack functions for comma lists are not intended to be mixed with the general ordered data functions detailed in the previous section: a comma list should either be used as an ordered data type or as a stack, but not in both ways.

\begin{verbatim}
\clist_get:NN \clist_get:cN \clist_get:NN \clist_get:cN
\end{verbatim}

Stores the left-most item from a \texttt{\comma list} in the \texttt{\token list variable} without removing it from the \texttt{\comma list}. The \texttt{\token list variable} is assigned locally. In the non-branching version, if the \texttt{\comma list} is empty the \texttt{\token list variable} is set to the marker value \texttt{\q_no_value}.

\begin{verbatim}
\clist_pop:NN \clist_pop:cN \clist_gpop:NN \clist_gpop:cN
\end{verbatim}

Pops the left-most item from a \texttt{\comma list} into the \texttt{\token list variable}, \texttt{i.e.} removes the item from the comma list and stores it in the \texttt{\token list variable}. Both of the variables are assigned locally.

\begin{verbatim}
\clist_pop:NNTF \clist_pop:cnTF \clist_pop:NNTF \clist_pop:cnTF
\end{verbatim}

If the \texttt{\comma list} is empty, leaves the \texttt{\false code} in the input stream. The value of the \texttt{\token list variable} is not defined in this case and should not be relied upon. If the \texttt{\comma list} is non-empty, pops the top item from the \texttt{\comma list} in the \texttt{\token list variable}, \texttt{i.e.} removes the item from the \texttt{\comma list}. Both the \texttt{\comma list} and the \texttt{\token list variable} are assigned locally.
If the \tokenlist is empty, leaves the (false code) in the input stream. The value of the \tokenvar is not defined in this case and should not be relied upon. If the \comma is non-empty, pops the top item from the \comma in the \tokenvar, i.e. removes the item from the \comma. The \comma is modified globally, while the \tokenvar is assigned locally.

8 Using a single item

Indexing items in the \comma from 1 at the top (left), this function evaluates the \intexp and leaves the appropriate item from the comma list in the input stream. If the \intexp is negative, indexing occurs from the bottom (right) of the comma list. When the \intexp is larger than the number of items in the \comma (as calculated by \clist_count:N) then the function expands to nothing.

\TeXhackers note: The result is returned within the \unexpanded primitive (\exp_not:n), which means that the \item does not expand further when appearing in an \x-type argument expansion.

9 Viewing comma lists

Displays the entries in the \comma in the terminal.
\clist_show:n \clist_log:N \clist_log:n

Displays the entries in the comma list in the terminal.

\clist_log:N \clist_log:n
Writes the entries in the comma list in the log file. See also \clist_show:n which displays the result in the terminal.

\clist_log:n
Writes the entries in the comma list in the log file. See also \clist_show:n which displays the result in the terminal.

\c_empty_clist
Constant that is always empty.

\l_tmpa_clist \l_tmpb_clist
Scratch comma lists for local assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

\g_tmpa_clist \g_tmpb_clist
Scratch comma lists for global assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

10 Constant and scratch comma lists
Part XVI

The l3token package

Token manipulation

This module deals with tokens. Now this is perhaps not the most precise description so let’s try with a better description: When programming in \TeX, it is often desirable to know just what a certain token is: is it a control sequence or something else. Similarly one often needs to know if a control sequence is expandable or not, a macro or a primitive, how many arguments it takes etc. Another thing of great importance (especially when it comes to document commands) is looking ahead in the token stream to see if a certain character is present and maybe even remove it or disregard other tokens while scanning. This module provides functions for both and as such has two primary function categories: \texttt{token} for anything that deals with tokens and \texttt{peek} for looking ahead in the token stream.

Most functions we describe here can be used on control sequences, as those are tokens as well.

It is important to distinguish two aspects of a token: its “shape” (for lack of a better word), which affects the matching of delimited arguments and the comparison of token lists containing this token, and its “meaning”, which affects whether the token expands or what operation it performs. One can have tokens of different shapes with the same meaning, but not the converse.

For instance, \texttt{\if:w}, \texttt{\if_charcode:w}, and \texttt{\tex_if:D} are three names for the same internal operation of \TeX, namely the primitive testing the next two characters for equality of their character code. They have the same meaning hence behave identically in many situations. However, \TeX distinguishes them when searching for a delimited argument. Namely, the example function \texttt{\show_until_if:w} defined below takes everything until \texttt{\if:w} as an argument, despite the presence of other copies of \texttt{\if:w} under different names.

\begin{verbatim}
\cs_new:Npn \show_until_if:w #1 \if:w { \tl_show:n {#1} }
\show_until_if:w \tex_if:D \if_charcode:w \if:w
\end{verbatim}

A list of all possible shapes and a list of all possible meanings are given in section 7.

1 Creating character tokens

\texttt{\char_set_active_eq:NN} ⟨char⟩ ⟨function⟩

Sets the behaviour of the ⟨char⟩ in situations where it is active (category code 13) to be equivalent to that of the ⟨function⟩. The category code of the ⟨char⟩ is unchanged by this process. The ⟨function⟩ may itself be an active character.

\texttt{\char_set_active_eq:Nc} ⟨char⟩ ⟨function⟩

\texttt{\char_set_active_eq:nn} ⟨integer expression⟩ ⟨function⟩

Sets the behaviour of the ⟨char⟩ which has character code as given by the ⟨integer expression⟩ in situations where it is active (category code 13) to be equivalent to that of the ⟨function⟩. The category code of the ⟨char⟩ is unchanged by this process. The ⟨function⟩ may itself be an active character.
\char_generate:nn \{charcode\} \{catcode\}

Generates a character token of the given \textit{charcode} and \textit{catcode} (both of which may be integer expressions). The \textit{catcode} may be one of

- 1 (begin group)
- 2 (end group)
- 3 (math toggle)
- 4 (alignment)
- 6 (parameter)
- 7 (math superscript)
- 8 (math subscript)
- 11 (letter)
- 12 (other)
- 13 (active)

and other values raise an error. The \textit{charcode} may be any one valid for the engine in use. Active characters cannot be generated in older versions of \texttt{Xe\LaTeX}.

**\TeX** hackers note:** Exactly two expansions are needed to produce the character.

\char_lowercase:N \langle \textit{char} \rangle

Converts the \textit{char} to the equivalent case-changed character as detailed by the function name (see \texttt{\str_foldcase:n} and \texttt{\text_titlecase:n} for details of these terms). The case mapping is carried out with no context-dependence (\textit{cf.} \texttt{\textuppercasenonzero:n}, etc.) The \texttt{str} versions always generate “other” (category code 12) characters, whilst the standard versions generate characters with the category code of the \texttt{char} (i.e. only the character code changes).

\c_catcode_other_space_tl

Token list containing one character with category code 12, (“other”), and character code 32 (space).
# 2 Manipulating and interrogating character tokens

\char_set_catcode_escape:N \char_set_catcode_letter:N \langle \text{character} \rangle

\char_set_catcode_group_begin:N \char_set_catcode_group_end:N
\char_set_catcode_math_toggle:N \char_set_catcode_alignment:N
\char_set_catcode_end_line:N \char_set_catcode_parameter:N
\char_set_catcode_math_superscript:N \char_set_catcode_math_subscript:N
\char_set_catcode_ignore:N \char_set_catcode_space:N
\char_set_catcode_letter:N \char_set_catcode_other:N
\char_set_catcode_comment:N \char_set_catcode_invalid:N

Sets the category code of the \langle \text{character} \rangle to that indicated in the function name. Depending on the current category code of the \langle \text{token} \rangle the escape token may also be needed:

```
\char_set_catcode_other:N \%%
```

The assignment is local.

\char_set_catcode_escape:n \char_set_catcode_letter:n \{ \langle \text{integer expression} \rangle \}

\char_set_catcode_group_begin:n \char_set_catcode_group_end:n
\char_set_catcode_math_toggle:n \char_set_catcode_alignment:n
\char_set_catcode_end_line:n \char_set_catcode_parameter:n
\char_set_catcode_math_superscript:n \char_set_catcode_math_subscript:n
\char_set_catcode_ignore:n \char_set_catcode_space:n
\char_set_catcode_letter:n \char_set_catcode_other:n
\char_set_catcode_active:n \char_set_catcode_comment:n \char_set_catcode_invalid:n

Sets the category code of the \langle \text{character} \rangle which has character code as given by the \langle \text{integer expression} \rangle. This version can be used to set up characters which cannot otherwise be given (cf. the \text{N}-type variants). The assignment is local.
These functions set the category code of the \textit{character} which has character code as given by the \textit{integer expression}. The first \textit{integer expression} is the character code and the second is the category code to apply. The setting applies within the current \TeX\ group. In general, the symbolic functions \texttt{\char_set_catcode\_\{type\}} should be preferred, but there are cases where these lower-level functions may be useful.

\begin{verbatim}
\char_set_catcode:nn \char_set_catcode:nn {(intexpr_1)} {(intexpr_2)}
\end{verbatim}

\begin{verbatim}
\char_value_catcode:n \char_value_catcode:n \{\textit{integer expression}\}
\end{verbatim}

\begin{verbatim}
\char_show_value_catcode:n \char_show_value_catcode:n \{\textit{integer expression}\}
\end{verbatim}

\begin{verbatim}
\char_set_lccode:nn \char_set_lccode:nn \{\textit{intexpr_1}\} \{\textit{intexpr_2}\}
\end{verbatim}

\begin{verbatim}
\char_value_lccode:n \char_value_lccode:n \{\textit{integer expression}\}
\end{verbatim}

\begin{verbatim}
\char_show_value_lccode:n \char_show_value_lccode:n \{\textit{integer expression}\}
\end{verbatim}

\begin{verbatim}
\char_set_uccode:nn \char_set_uccode:nn \{\textit{intexpr_1}\} \{\textit{intexpr_2}\}
\end{verbatim}

\begin{verbatim}
\char_value_uccode:n \char_value_uccode:n \{\textit{integer expression}\}
\end{verbatim}

\begin{verbatim}
\char_show_value_uccode:n \char_show_value_uccode:n \{\textit{integer expression}\}
\end{verbatim}

The setting applies within the current \TeX\ group.
\char_value_uccode:n \{\langle integer expression\rangle\}  
Expands to the current upper case code of the \langle character \rangle with character code given by the \langle integer expression \rangle.

\char_value_uccode:n * \{\langle integer expression\rangle\}  

\char_show_uccode:n \{\langle integer expression\rangle\}  
Displays the current upper case code of the \langle character \rangle with character code given by the \langle integer expression \rangle on the terminal.

\char_set_mathcode:nn \{\{intexpr\}_1\} \{\{intexpr\}_2\}  
Updated: 2015-08-06  
This function sets up the math code of \langle character \rangle. The \langle character \rangle is specified as an \langle integer expression \rangle which will be used as the character code of the relevant character. The setting applies within the current TeX group.

\char_value_mathcode:n \{\langle integer expression\rangle\}  
Expands to the current math code of the \langle character \rangle with character code given by the \langle integer expression \rangle.

\char_set_mathcode:nn \{\{intexpr\}_1\} \{\{intexpr\}_2\}  
Updated: 2015-08-06  
This function sets up the space factor for the \langle character \rangle. The \langle character \rangle is specified as an \langle integer expression \rangle which will be used as the character code of the relevant character. The setting applies within the current TeX group.

\char_value_sfcode:n \{\langle integer expression\rangle\}  
Expands to the current space factor for the \langle character \rangle with character code given by the \langle integer expression \rangle.

\char_set_sfcode:nn \{\{intexpr\}_1\} \{\{intexpr\}_2\}  
Updated: 2015-08-06  
This function sets up the space factor for the \langle character \rangle. The \langle character \rangle is specified as an \langle integer expression \rangle which will be used as the character code of the relevant character. The setting applies within the current TeX group.

\char_value_sfcode:n * \{\langle integer expression\rangle\}  

\char_show_sfcode:n \{\langle integer expression\rangle\}  
Displays the current space factor for the \langle character \rangle with character code given by the \langle integer expression \rangle on the terminal.

\l_char_active_seq  
New: 2012-01-23  
Updated: 2015-11-11  
Used to track which tokens may require special handling at the document level as they are (or have been at some point) of category \langle active \rangle (catcode 13). Each entry in the sequence consists of a single escaped token, for example \~. Active tokens should be added to the sequence when they are defined for general document use.

\l_char_special_seq  
New: 2012-01-23  
Updated: 2015-11-11  
Used to track which tokens will require special handling when working with verbatim-like material at the document level as they are not of categories \langle letter \rangle (catcode 11) or \langle other \rangle (catcode 12). Each entry in the sequence consists of a single escaped token, for example \\ for the backslash or \{ for an opening brace. Escaped tokens should be added to the sequence when they are defined for general document use.
3 Generic tokens

These are implicit tokens which have the category code described by their name. They are used internally for test purposes but are also available to the programmer for other uses.

\c_group_begin_token
\c_group_end_token
\c_math_toggle_token
\c_alignment_token
\c_parameter_token
\c_math_superscript_token
\c_math_subscript_token
\c_space_token

These are implicit tokens which have the category code described by their name. They are used internally for test purposes and should not be used other than for category code tests.

\c_catcode_letter_token
\c_catcode_other_token

A token list containing an active token. This is used internally for test purposes and should not be used other than in appropriately-constructed category code tests.

4 Converting tokens

\token_to_meaning:N \token_to_meaning:c

Inserts the current meaning of the \token into the input stream as a series of characters of category code 12 (other). This is the primitive \TeX description of the \token, thus for example both functions defined by \cs_set_nopar:Npn and token list variables defined using \tl_new:N are described as macros.

\TeXhackers note: This is the \TeX primitive \meaning. The \token can thus be an explicit space tokens or an explicit begin-group or end-group character token ({ or } when normal \TeX category codes apply) even though these are not valid \N-type arguments.

\token_to_str:N \token_to_str:c

Converts the given \token into a series of characters with category code 12 (other). If the \token is a control sequence, this will start with the current escape character with category code 12 (the escape character is part of the \token). This function requires only a single expansion.

\TeXhackers note: \token_to_str:N is the \TeX primitive \string renamed. The \token can thus be an explicit space tokens or an explicit begin-group or end-group character token ({ or } when normal \TeX category codes apply) even though these are not valid \N-type arguments.
5 Token conditionals

Tests if \(\text{token}\) has the category code of a begin group token \(\{\text{true code}\}\) \(\{\text{false code}\}\)

Tests if \(\text{token}\) has the category code of an end group token \(\}\text{true code}\}\) \(\}\text{false code}\}\)

Tests if \(\text{token}\) has the category code of a math shift token \(\$\text{true code}\}\) \(\$\text{false code}\}\)

Tests if \(\text{token}\) has the category code of an alignment token \(\&\text{true code}\}\) \(\&\text{false code}\}\)

Tests if \(\text{token}\) has the category code of a macro parameter token \(\#\text{true code}\}\) \(\#\text{false code}\}\)

Tests if \(\text{token}\) has the category code of a superscript token \(^\text{true code}\}\) \(^\text{false code}\}\)

Tests if \(\text{token}\) has the category code of a subscript token \(_\text{true code}\}\) \(_\text{false code}\}\)

Tests if \(\text{token}\) has the category code of a space token. Note that an explicit space token with character code 32 cannot be tested in this way, as it is not a valid \(\text{N}\)-type argument. 

Tests if \(\text{token}\) has the category code of a begin group token \(\{\text{true code}\}\) \(\{\text{false code}\}\)

Tests if \(\text{token}\) has the category code of an end group token \(\}\text{true code}\}\) \(\}\text{false code}\}\)

Tests if \(\text{token}\) has the category code of a math shift token \(\$\text{true code}\}\) \(\$\text{false code}\}\)

Tests if \(\text{token}\) has the category code of an alignment token \(\&\text{true code}\}\) \(\&\text{false code}\}\)

Tests if \(\text{token}\) has the category code of a macro parameter token \(\#\text{true code}\}\) \(\#\text{false code}\}\)

Tests if \(\text{token}\) has the category code of a superscript token \(^\text{true code}\}\) \(^\text{false code}\}\)

Tests if \(\text{token}\) has the category code of a subscript token \(_\text{true code}\}\) \(_\text{false code}\}\)

Tests if \(\text{token}\) has the category code of a space token. Note that an explicit space token with character code 32 cannot be tested in this way, as it is not a valid \(\text{N}\)-type argument.
Tests if (token) has the category code of a letter token.

Tests if (token) has the category code of an “other” token.

Tests if (token) has the category code of an active character.

Tests if the two (tokens) have the same category code.

Tests if the two (tokens) have the same character code.

Tests if the two (tokens) have the same meaning when expanded.

Tests if the (token) is a \TeX{} macro.

Tests if the (token) is a control sequence.

Tests if the (token) is expandable. This test returns \emph{false} for an undefined token.

Tests if the (token) is a long macro.

Tests if the (token) is a protected macro: for a macro which is both protected and long this returns \emph{false}.
Tests if the \textit{token} is a protected long macro.

Tests if the \textit{token} is defined to be a chardef.

\textbf{TeXhackers note:} Boolean, boxes and small integer constants are implemented as \texttt{chardefs}.

Tests if the \textit{token} is defined to be a mathchardef.

Tests if the \textit{token} is defined to be a dimension register.

Tests if the \textit{token} is defined to be an integer register.

\textbf{TeXhackers note:} Constant integers may be implemented as integer registers, \texttt{chardefs}, or \texttt{mathchardefs} depending on their value.

Tests if the \textit{token} is defined to be a muskip register.

Tests if the \textit{token} is defined to be a skip register.
Tests if the \langle token \rangle is defined to be a toks register (not used by \LaTeX3).

Tests if the \langle token \rangle is an engine primitive.

6 Peeking ahead at the next token

There is often a need to look ahead at the next token in the input stream while leaving it in place. This is handled using the “peek” functions. The generic \texttt{\peek_after:Nw} is provided along with a family of predefined tests for common cases. As peeking ahead does not skip spaces the predefined tests include both a space-respecting and space-skipping version.

\texttt{\peek_after:Nw} \langle function \rangle \langle token \rangle

Locally sets the test variable \texttt{\_l\_peek_token} equal to \langle token \rangle (as an implicit token, \textit{not} as a token list), and then expands the \langle function \rangle. The \langle token \rangle remains in the input stream as the next item after the \langle function \rangle. The \langle token \rangle here may be \_l, \{ or \} (assuming normal \TeX category codes), \textit{i.e.} it is not necessarily the next argument which would be grabbed by a normal function.

\texttt{\peek_gafter:Nw} \langle function \rangle \langle token \rangle

Globally sets the test variable \texttt{\_g\_peek_token} equal to \langle token \rangle (as an implicit token, \textit{not} as a token list), and then expands the \langle function \rangle. The \langle token \rangle remains in the input stream as the next item after the \langle function \rangle. The \langle token \rangle here may be \_l, \{ or \} (assuming normal \TeX category codes), \textit{i.e.} it is not necessarily the next argument which would be grabbed by a normal function.

\texttt{\_l\_peek_token} Token set by \texttt{\peek_after:Nw} and available for testing as described above.

\texttt{\_g\_peek_token} Token set by \texttt{\peek_gafter:Nw} and available for testing as described above.

\texttt{\peek_catcode:NTF} \langle test token \rangle \langle (true code) \rangle \langle (false code) \rangle

Tests if the next \langle token \rangle in the input stream has the same category code as the \langle test token \rangle (as defined by the test \texttt{\token_if_eq_catcode:NNTF}). Spaces are respected by the test and the \langle token \rangle is left in the input stream after the \langle true code \rangle or \langle false code \rangle (as appropriate to the result of the test).
\peek_catcode_ignore_spaces:NTF \peek_catcode_ignore_spaces:NTF \test token \{\true code\} \{\false code\}

Tests if the next non-space \token in the input stream has the same category code as the \test token (as defined by the test \token_if_eq_catcode:NNTF). Explicit and implicit space tokens (with character code 32 and category code 10) are ignored and removed by the test and the \token is left in the input stream after the \true code or \false code (as appropriate to the result of the test).

\peek_catcode_remove:NTF \peek_catcode_remove:NTF \test token \{\true code\} \{\false code\}

Tests if the next \token in the input stream has the same category code as the \test token (as defined by the test \token_if_eq_catcode:NNTF). Spaces are respected by the test and the \token is removed from the input stream if the test is true. The function then places either the \true code or \false code in the input stream (as appropriate to the result of the test).

\peek_catcode_remove_ignore_spaces:NTF \peek_catcode_remove_ignore_spaces:NTF \test token \{\true code\} \{\false code\}

Tests if the next non-space \token in the input stream has the same category code as the \test token (as defined by the test \token_if_eq_catcode:NNTF). Explicit and implicit space tokens (with character code 32 and category code 10) are ignored and removed by the test and the \token is removed from the input stream if the test is true. The function then places either the \true code or \false code in the input stream (as appropriate to the result of the test).

\peek_charcode:NTF \peek_charcode:NTF \test token \{\true code\} \{\false code\}

Tests if the next \token in the input stream has the same character code as the \test token (as defined by the test \token_if_eq_charcode:NNTF). Spaces are respected by the test and the \token is left in the input stream after the \true code or \false code (as appropriate to the result of the test).

\peek_charcode_remove:NTF \peek_charcode_remove:NTF \test token \{\true code\} \{\false code\}

Tests if the next \token in the input stream has the same character code as the \test token (as defined by the test \token_if_eq_charcode:NNTF). Spaces are respected by the test and the \token is removed from the input stream if the test is true. The function then places either the \true code or \false code in the input stream (as appropriate to the result of the test).
Tests if the next non-space ⟨token⟩ in the input stream has the same character code as the ⟨test token⟩ (as defined by the test \token_if_eq_charcode:NNTF). Explicit and implicit space tokens (with character code 32 and category code 10) are ignored and removed by the test and the ⟨token⟩ is removed from the input stream if the test is true. The function then places either the ⟨true code⟩ or ⟨false code⟩ in the input stream (as appropriate to the result of the test).

Tests if the next ⟨token⟩ in the input stream has the same meaning as the ⟨test token⟩ (as defined by the test \token_if_eq_meaning:NNTF). Spaces are respected by the test and the ⟨token⟩ is left in the input stream after the ⟨true code⟩ or ⟨false code⟩ (as appropriate to the result of the test).

Tests if the next non-space ⟨token⟩ in the input stream has the same meaning as the ⟨test token⟩ (as defined by the test \token_if_eq_meaning:NNTF). Explicit and implicit space tokens (with character code 32 and category code 10) are ignored and removed by the test and the ⟨token⟩ is removed from the input stream if the test is true. The function then places either the ⟨true code⟩ or ⟨false code⟩ in the input stream (as appropriate to the result of the test).

Tests if the next ⟨token⟩ in the input stream has the same meaning as the ⟨test token⟩ (as defined by the test \token_if_eq_meaning:NNTF). Spaces are respected by the test and the ⟨token⟩ is removed from the input stream if the test is true. The function then places either the ⟨true code⟩ or ⟨false code⟩ in the input stream (as appropriate to the result of the test).

Tests if the next non-space ⟨token⟩ in the input stream has the same meaning as the ⟨test token⟩ (as defined by the test \token_if_eq_meaning:NNTF). Explicit and implicit space tokens (with character code 32 and category code 10) are ignored and removed by the test and the ⟨token⟩ is removed from the input stream if the test is true. The function then places either the ⟨true code⟩ or ⟨false code⟩ in the input stream (as appropriate to the result of the test).
\peek\_N\_type:TF \{\langle true code \rangle \} \{\langle false code \rangle \}
Tests if the next \langle token \rangle in the input stream can be safely grabbed as an \textit{N}-type argument. The test is \langle false \rangle if the next \langle token \rangle is either an explicit or implicit begin-group or end-group token (with any character code), or an explicit or implicit space character (with character code 32 and category code 10), or an outer token (never used in \LaTeX{}3) and \langle true \rangle in all other cases. Note that a \langle true \rangle result ensures that the next \langle token \rangle is a valid \textit{N}-type argument. However, if the next \langle token \rangle is for instance \texttt{\_c\_space\_token}, the test takes the \langle false \rangle branch, even though the next \langle token \rangle is in fact a valid \textit{N}-type argument. The \langle token \rangle is left in the input stream after the \langle true code \rangle or \langle false code \rangle (as appropriate to the result of the test).

7 Description of all possible tokens

Let us end by reviewing every case that a given token can fall into. This section is quite technical and some details are only meant for completeness. We distinguish the meaning of the token, which controls the expansion of the token and its effect on \LaTeX{}’s state, and its shape, which is used when comparing token lists such as for delimited arguments. Two tokens of the same shape must have the same meaning, but the converse does not hold.

A token has one of the following shapes.

- A control sequence, characterized by the sequence of characters that constitute its name: for instance, \texttt{\_use\_n} is a five-letter control sequence.
- An active character token, characterized by its character code (between 0 and 1114111 for \texttt{luatex} and \texttt{xetex} and less for other engines) and category code 13.
- A character token, characterized by its character code and category code (one of 1, 2, 3, 4, 6, 7, 8, 10, 11 or 12 whose meaning is described below).\footnote{In \texttt{luatex}, there is also the case of “bytes”, which behave as character tokens of category code 12 (other) and character code between 1114112 and 1114366. They are used to output individual bytes to files, rather than UTF-8.}

There are also a few internal tokens. The following list may be incomplete in some engines.

- Expanding \texttt{\_the\_font} results in a token that looks identical to the command that was used to select the current font (such as \texttt{\_tenrm}) but it differs from it in shape.
- A “frozen” \texttt{\_relax}, which differs from the primitive in shape (but has the same meaning), is inserted when the closing \texttt{\_fi} of a conditional is encountered before the conditional is evaluated.
- Expanding \texttt{\_noexpand} \langle token \rangle (when the \langle token \rangle is expandable) results in an internal token, displayed (temporarily) as \texttt{\_notexpanded: \langle token \rangle}, whose shape coincides with the \langle token \rangle and whose meaning differs from \texttt{\_relax}.
- An \texttt{\_outer\_endtemplate}: can be encountered when peeking ahead at the next token; this expands to another internal token, \texttt{\_end\_alignment\_template}.
- Tricky programming might access a frozen \texttt{\_endwrite}.
Some frozen tokens can only be accessed in interactive sessions: \cr, \right, \endgroup, \fi, \inaccessible.

The meaning of a (non-active) character token is fixed by its category code (and character code) and cannot be changed. We call these tokens explicit character tokens. Category codes that a character token can have are listed below by giving a sample output of the \TeX primitive \meaning, together with their \LaTeX3 names and most common example:

1. begin-group character (\group_begin, often \{),
2. end-group character (\group_end, often \}),
3. math shift character (\math_toggle, often $),
4. alignment tab character (\alignment, often &),
5. macro parameter character (\parameter, often #),
6. superscript character (\math_superscript, often ^),
7. subscript character (\math_subscript, often _),
8. blank space (space, often character code 32),
9. the letter (letter, such as A),
10. the character (other, such as 0).

Category code 13 (active) is discussed below. Input characters can also have several other category codes which do not lead to character tokens for later processing:

0 (escape), 5 (end_line), 9 (ignore), 14 (comment), and 15 (invalid).

The meaning of a control sequence or active character can be identical to that of any character token listed above (with any character code), and we call such tokens implicit character tokens. The meaning is otherwise in the following list:

- a macro, used in \LaTeX3 for most functions and some variables (tl, fp, seq, ...),
- a primitive such as \def or \topmark, used in \LaTeX3 for some functions,
- a register such as \count123, used in \LaTeX3 for the implementation of some variables (int, dim, ...),
- a constant integer such as \char"56 or \mathchar"121,
- a font selection command,
- undefined.

Macros be \protected or not, \long or not (the opposite of what \LaTeX3 calls \nopar), and \outer or not (unused in \LaTeX3). Their \meaning takes the form

\langle properties \rangle macro: \langle parameters \rangle \rightarrow \langle replacement \rangle
where \( \langle \text{properties} \rangle \) is among \texttt{\textbackslash protected\textbackslash long\textbackslash outer}, \( \langle \text{parameters} \rangle \) describes parameters that the macro expects, such as \#1\#2\#3, and \( \langle \text{replacement} \rangle \) describes how the parameters are manipulated, such as \#2/#1/#3.

Now is perhaps a good time to mention some subtleties relating to tokens with category code 10 (space). Any input character with this category code (normally, space and tab characters) becomes a normal space, with character code 32 and category code 10.

When a macro takes an undelimited argument, explicit space characters (with character code 32 and category code 10) are ignored. If the following token is an explicit character token with category code 1 (begin-group) and an arbitrary character code, then \TeX{} scans ahead to obtain an equal number of explicit character tokens with category code 1 (begin-group) and 2 (end-group), and the resulting list of tokens (with outer braces removed) becomes the argument. Otherwise, a single token is taken as the argument for the macro: we call such single tokens “N-type”, as they are suitable to be used as an argument for a function with the signature :N.
Part XVII

The l3prop package

Property lists

\LaTeX3 implements a “property list” data type, which contain an unordered list of entries each of which consists of a ⟨key⟩ and an associated ⟨value⟩. The ⟨key⟩ and ⟨value⟩ may both be any ⟨balanced text⟩. It is possible to map functions to property lists such that the function is applied to every key–value pair within the list.

Each entry in a property list must have a unique ⟨key⟩: if an entry is added to a property list which already contains the ⟨key⟩ then the new entry overwrites the existing one. The ⟨keys⟩ are compared on a string basis, using the same method as \texttt{str_if_eq:n}.\n
Property lists are intended for storing key-based information for use within code. This is in contrast to key–value lists, which are a form of input parsed by the \texttt{keys} module.

1 Creating and initialising property lists

\begin{verbatim}
\prop_new:N \prop_new:c \prop_clear:N \prop_clear:c \prop_clear:N \prop_clear:c \prop_gclear:N \prop_gclear:c \prop_set_eq:NN \prop_set_eq:cn \prop_gset_eq:NN \prop_gset_eq:cn \prop_set_from_keyval:Nn \prop_set_from_keyval:cn \prop_gset_from_keyval:Nn \prop_gset_from_keyval:cn
\end{verbatim}

\texttt{\prop_new:N} ⟨property list⟩

Creates a new ⟨property list⟩ or raises an error if the name is already taken. The declaration is global. The ⟨property list⟩ initially contains no entries.

\texttt{\prop_clear:N} ⟨property list⟩

Clears all entries from the ⟨property list⟩.

\texttt{\prop_gclear:N} ⟨property list⟩

Ensures that the ⟨property list⟩ exists globally by applying \texttt{\prop_new:N} if necessary, then applies \texttt{\prop_gclear:N} to leave the list empty.

\texttt{\prop_set_eq:NN} ⟨property list$_1$⟩ ⟨property list$_2$⟩

Sets the content of ⟨property list$_1$⟩ equal to that of ⟨property list$_2$⟩.

\texttt{\prop_set_from_keyval:Nn} ⟨prop var⟩

\{ ⟨key1⟩ = ⟨value1⟩ , ⟨key2⟩ = ⟨value2⟩ , \ldots \}

Sets ⟨prop var⟩ to contain key–value pairs given in the second argument. If duplicate keys appear only one of the values is kept.
\prop_const_from_keyval:Nn \prop_const_from_keyval:cn

New: 2017-11-28
Updated: 2019-08-25

\prop_const_from_keyval:Nn (prop var)
\{
  \langle key1 \rangle = \langle value1 \rangle ,
  \langle key2 \rangle = \langle value2 \rangle , ... 
\}

Creates a new constant \langle prop var \rangle or raises an error if the name is already taken. The \langle prop var \rangle is set globally to contain key–value pairs given in the second argument. If duplicate keys appear only one of the values is kept.

2 Adding entries to property lists

\prop_put:Nnn \prop_put:N
\prop_put:(NnV|Nno|Nnx|NVn|NVV|Non|Noo|cnn|cnV|cno|cnx|cVn|cVV|con|coo)

Updated: 2012-07-09

Adds an entry to the \langle property list \rangle which may be accessed using the \langle key \rangle and which has \langle value \rangle. Both the \langle key \rangle and \langle value \rangle may contain any \langle balanced text \rangle. The \langle key \rangle is stored after processing with \tl_to_str:n, meaning that category codes are ignored. If the \langle key \rangle is already present in the \langle property list \rangle, the existing entry is overwritten by the new \langle value \rangle.

\prop_put_if_new:Nnn \prop_put_if_new:N
\prop_put_if_new:cn \prop_gput_if_new:Nnn \prop_gput_if_new:cnn

\prop_gput:Nnn \prop_gput:N
\prop_gput:(NnV|Nno|Nnx|NVn|NVV|Non|Noo|cnn|cnV|cno|cnx|cVn|cVV|con|coo)

Updated: 2012-07-09

If the \langle key \rangle is present in the \langle property list \rangle then no action is taken. If the \langle key \rangle is not present in the \langle property list \rangle then a new entry is added. Both the \langle key \rangle and \langle value \rangle may contain any \langle balanced text \rangle. The \langle key \rangle is stored after processing with \tl_to_str:n, meaning that category codes are ignored.

3 Recovering values from property lists

\prop_get:NnN \prop_get:N
\prop_get:(NVN|NoN|cnV|cno)

Updated: 2011-08-28

Recovers the \langle value \rangle stored with \langle key \rangle from the \langle property list \rangle, and places this in the \langle token list variable \rangle. If the \langle key \rangle is not found in the \langle property list \rangle then the \langle token list variable \rangle is set to the special marker \q_no_value. The \langle token list variable \rangle is set within the current \TeX{} group. See also \prop_get:NnNTF.

\prop_pop:NnN \prop_pop:Nn \prop_pop:(NoN|cnV|cno)

Updated: 2011-08-18

Recovers the \langle value \rangle stored with \langle key \rangle from the \langle property list \rangle, and places this in the \langle token list variable \rangle. If the \langle key \rangle is not found in the \langle property list \rangle then the \langle token list variable \rangle is set to the special marker \q_no_value. The \langle key \rangle and \langle value \rangle are then deleted from the property list. Both assignments are local. See also \prop_pop:NnNTF.
\prop_gpop:NnN
\prop_gpop:(NoN)[cn][coN]

\prop_gpop:Nn \{property list\} \{(key)\} \{tl var\}
Recovers the \langle value \rangle stored with \langle key \rangle from the \langle property list \rangle, and places this in the \langle token list variable \rangle. If the \langle key \rangle is not found in the \langle property list \rangle then the \langle token list variable \rangle is set to the special marker \q_no_value. The \langle key \rangle and \langle value \rangle are then deleted from the property list. The \langle property list \rangle is modified globally, while the assignment of the \langle token list variable \rangle is local. See also \prop_gpop:NnNTF.

\prop_item:Nn * \prop_item:cn *

\prop_item:Nn \{property list\} \{(key)\}
Expands to the \langle value \rangle corresponding to the \langle key \rangle in the \langle property list \rangle. If the \langle key \rangle is missing, this has an empty expansion.

\TeXhackers note: This function is slower than the non-expandable analogue \prop_get:Nn. The result is returned within the \unexpanded primitive \exp_not:n, which means that the \langle value \rangle does not expand further when appearing in an x-type argument expansion.

\prop_count:N * \prop_count:c *

\prop_count:N \{property list\}
Leaves the number of key–value pairs in the \langle property list \rangle in the input stream as an \langle integer denotation \rangle.

4 Modifying property lists

\prop_remove:Nn \{property list\} \{(key)\}
Removes the entry listed under \langle key \rangle from the \langle property list \rangle. If the \langle key \rangle is not found in the \langle property list \rangle no change occurs, i.e there is no need to test for the existence of a key before deleting it.

5 Property list conditionals

\prop_if_exist_p:N * \prop_if_exist_p:c *
\prop_if_exist:NTF * \prop_if_exist:cTF *

\prop_if_exist_p:N \{property list\}
\prop_if_exist:NTF \{true code\} \{false code\}
Tests whether the \langle property list \rangle is currently defined. This does not check that the \langle property list \rangle really is a property list variable.

\prop_if_empty_p:N * \prop_if_empty_p:c *
\prop_if_empty:NTF * \prop_if_empty:cTF *

\prop_if_empty_p:N \{property list\}
\prop_if_empty:NTF \{true code\} \{false code\}
Tests if the \langle property list \rangle is empty (containing no entries).
Tests if the \langle key \rangle is present in the \langle property list \rangle, making the comparison using the method described by \str_if_eq:nnTF.

\textbf{\textsc{TeX}hackers note:} This function iterates through every key–value pair in the \langle property list \rangle and is therefore slower than using the non-expandable \prop_get:NnNTF.

6 Recovering values from property lists with branching

The functions in this section combine tests for the presence of a key in a property list with recovery of the associated valued. This makes them useful for cases where different cases follow dependent on the presence or absence of a key in a property list. They offer increased readability and performance over separate testing and recovery phases.

If the \langle key \rangle is not present in the \langle property list \rangle, leaves the \langle false code \rangle in the input stream. The value of the \langle token list variable \rangle is not defined in this case and should not be relied upon. If the \langle key \rangle is present in the \langle property list \rangle, pops the corresponding \langle value \rangle in the \langle token list variable \rangle, i.e. removes the item from the \langle property list \rangle. Both the \langle property list \rangle and the \langle token list variable \rangle are assigned locally.
7 Mapping to property lists

All mappings are done at the current group level, i.e. any local assignments made by the \langle function \rangle or \langle code \rangle discussed below remain in effect after the loop.

\textbf{prop_map_function:NN}\quad \textbf{prop_map_function:CN}\quad \text{Updated: 2013-01-08}

Applies \langle function \rangle to every \langle entry \rangle stored in the \langle property list \rangle. The \langle function \rangle receives two arguments for each iteration: the \langle key \rangle and associated \langle value \rangle. The order in which \langle entries \rangle are returned is not defined and should not be relied upon. To pass further arguments to the \langle function \rangle, see \textbf{prop_map_tokens:Nn}.

\textbf{prop_map_inline:Nn}\quad \textbf{prop_map_inline:CN}\quad \text{Updated: 2013-01-08}

Applies \langle inline function \rangle to every \langle entry \rangle stored within the \langle property list \rangle. The \langle inline function \rangle should consist of code which receives the \langle key \rangle as \#1 and the \langle value \rangle as \#2. The order in which \langle entries \rangle are returned is not defined and should not be relied upon.

\textbf{prop_map_tokens:Nn}\quad \textbf{prop_map_tokens:CN}\quad \text{Updated: 2012-06-29}

Analogue of \textbf{prop_map_function:NN} which maps several tokens instead of a single function. The \langle code \rangle receives each key–value pair in the \langle property list \rangle as two trailing brace groups. For instance,

\texttt{\prop_map_tokens:Nn \l_my_prop \{ \str_if_eq:nnT \{ mykey \} \}}

expands to the value corresponding to mykey: for each pair in \l_my_prop the function \str_if_eq:nnT receives mykey, the \langle key \rangle and the \langle value \rangle as its three arguments. For that specific task, \textbf{prop_item:Nn} is faster.

\textbf{prop_map_break}:\quad \text{Updated: 2012-06-29}

Used to terminate a \textbf{prop_map_...} function before all entries in the \langle property list \rangle have been processed. This normally takes place within a conditional statement, for example

\texttt{\prop_map_inline:Nn \l_my_prop \{}
    \str_if_eq:nTF \{ \#1 \} \{ bingo \}
    \{ \prop_map_break: \}
    \{% Do something useful \}
\}

Use outside of a \textbf{prop_map_...} scenario leads to low level \TeX errors.

\textbf{\TeXhacksnote}: When the mapping is broken, additional tokens may be inserted before further items are taken from the input stream. This depends on the design of the mapping function.
\prop_map_break:n \{\text{code}\}

Used to terminate a \prop_map... function before all entries in the \langle property list \rangle have been processed, inserting the \langle code \rangle after the mapping has ended. This normally takes place within a conditional statement, for example

\prop_map_inline:Nn \l_my_prop
{\str_if_eq:nnTF { #1 } { bingo }
{ \prop_map_break:n \{ <\text{code}> \} }
{ % Do something useful
}
}

Use outside of a \prop_map... scenario leads to low level \TeX errors.

\textit{\TeX hackers note:} When the mapping is broken, additional tokens may be inserted before the \langle code \rangle is inserted into the input stream. This depends on the design of the mapping function.

8 Viewing property lists

\prop_show:N \prop_show:c

Displayed in the terminal.

\prop_log:N \prop_log:c

Written to the log file.

9 Scratch property lists

\l_tmpa_prop \l_tmpb_prop

Scratch property lists for local assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

\g_tmpa_prop \g_tmpb_prop

Scratch property lists for global assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.
10 Constants

\c_empty_prop A permanently-empty property list used for internal comparisons.
Part XVIII
The l3msg package
Messages

Messages need to be passed to the user by modules, either when errors occur or to indicate how the code is proceeding. The l3msg module provides a consistent method for doing this (as opposed to writing directly to the terminal or log).

The system used by l3msg to create messages divides the process into two distinct parts. Named messages are created in the first part of the process; at this stage, no decision is made about the type of output that the message will produce. The second part of the process is actually producing a message. At this stage a choice of message class has to be made, for example error, warning or info.

By separating out the creation and use of messages, several benefits are available. First, the messages can be altered later without needing details of where they are used in the code. This makes it possible to alter the language used, the detail level and so on. Secondly, the output which results from a given message can be altered. This can be done on a message class, module or message name basis. In this way, message behaviour can be altered and messages can be entirely suppressed.

1 Creating new messages

All messages have to be created before they can be used. The text of messages is automatically wrapped to the length available in the console. As a result, formatting is only needed where it helps to show meaning. In particular, \ may be used to force a new line and \ forces an explicit space. Additionally, \#, \%, \ and \- can be used to produce the corresponding character.

Messages may be subdivided by one level using the / character. This is used within the message filtering system to allow for example the \LaTeX \ kernel messages to belong to the module \LaTeX \ while still being filterable at a more granular level. Thus for example

\msg_new:nnnn { mymodule } { submodule / message } ...

will allow to filter out specifically messages from the submodule.
Tests whether the \textit{message} for the \textit{module} is currently defined.

\section{Contextual information for messages}

\texttt{\msg_line_context}:

Prints the current line number when a message is given, and thus suitable for giving context to messages. The number itself is proceeded by the text \textit{on line}.

\texttt{\msg_line_number}:

Prints the current line number when a message is given.

\texttt{\msg_fatal_text:n} \{\textit{module}\}

Produces the standard text

\textbf{Fatal Package }\textit{\texttt{(module)} Error}

This function can be redefined to alter the language in which the message is given, using \#1 as the name of the \textit{\langle module\rangle} to be included.

\texttt{\msg_critical_text:n} \{\textit{module}\}

Produces the standard text

\textbf{Critical Package }\textit{\texttt{(module)} Error}

This function can be redefined to alter the language in which the message is given, using \#1 as the name of the \textit{\langle module\rangle} to be included.

\texttt{\msg_error_text:n} \{\textit{module}\}

Produces the standard text

\textbf{Package }\textit{\texttt{(module)} Error}

This function can be redefined to alter the language in which the message is given, using \#1 as the name of the \textit{\langle module\rangle} to be included.

\texttt{\msg_warning_text:n} \{\textit{module}\}

Produces the standard text

\textbf{Package }\textit{\texttt{(module)} Warning}

This function can be redefined to alter the language in which the message is given, using \#1 as the name of the \textit{\langle module\rangle} to be included. The \textit{\langle type\rangle} of \textit{\langle module\rangle} may be adjusted: Package is the standard outcome: see \texttt{\msg_module_type:n}. 

\thispagestyle{plain}

151
\msg_info_text:n \msg_info_text:n {⟨module⟩}

Produces the standard text:

Package ⟨module⟩ Info

This function can be redefined to alter the language in which the message is given, using #1 as the name of the ⟨module⟩ to be included. The ⟨type⟩ of ⟨module⟩ may be adjusted:

Package is the standard outcome: see \msg_module_type:n.

\msg_module_name:n \msg_module_name:n {⟨module⟩}

Expands to the public name of the ⟨module⟩ as defined by \g_msg_module_name_prop (or otherwise leaves the ⟨module⟩ unchanged).

\msg_module_type:n \msg_module_type:n {⟨module⟩}

Expands to the description which applies to the ⟨module⟩, for example a Package or Class. The information here is defined in \g_msg_module_type_prop, and will default to Package if an entry is not present.

\msg_see_documentation_text:n \msg_see_documentation_text:n {⟨module⟩}

Produces the standard text

See the ⟨module⟩ documentation for further information.

This function can be redefined to alter the language in which the message is given, using #1 as the name of the ⟨module⟩ to be included. The name of the ⟨module⟩ may be altered by use of \g_msg_module_documentation_prop

\g_msg_module_name_prop

Provides a mapping between the module name used for messages, and that for documentation. For example, \LaTeX{}3 core messages are stored in the reserved \LaTeX{} tree, but are printed as \LaTeX{}3.

\g_msg_module_type_prop

Provides a mapping between the module name used for messages, and that type of module. For example, for \LaTeX{}3 core messages, an empty entry is set here meaning that they are not described using the standard Package text.

3 Issuing messages

Messages behave differently depending on the message class. In all cases, the message may be issued supplying 0 to 4 arguments. If the number of arguments supplied here does not match the number in the definition of the message, extra arguments are ignored, or empty arguments added (of course the sense of the message may be impaired). The four arguments are converted to strings before being added to the message text: the x-type variants should be used to expand material.
\msg_fatal:nnnnnn \{module\} \{message\} \{arg one\} \{arg two\} \{arg three\} \{arg four\}

Issues \textit{(module)} error \textit{(message)}, passing \textit{(arg one)} to \textit{(arg four)} to the text-creating functions. After issuing a fatal error the \TeX{} run halts. No PDF file will be produced in this case (DVI mode runs may produce a truncated DVI file).

\TeX{}hackers note: The \TeX{} \texttt{\endinput} primitive is used to exit the file. In particular, the rest of the current line remains in the input stream.

\msg_error:nnnnnn \{module\} \{message\} \{arg one\} \{arg two\} \{arg three\} \{arg four\}

Issues \textit{(module)} error \textit{(message)}, passing \textit{(arg one)} to \textit{(arg four)} to the text-creating functions. The error interrupts processing and issues the text at the terminal. After user input, the run continues.

\msg_warning:nnnnnn \{module\} \{message\} \{arg one\} \{arg two\} \{arg three\} \{arg four\}

Issues \textit{(module)} warning \textit{(message)}, passing \textit{(arg one)} to \textit{(arg four)} to the text-creating functions. The warning text is added to the log file and the terminal, but the \TeX{} run is not interrupted.
4 Redirecting messages

Each message has a “name”, which can be used to alter the behaviour of the message when it is given. Thus we might have

\msg_new:nnnn { module } { my-message } { Some-text } { Some-more-text }

to define a message, with

\msg_error:nn { module } { my-message }

when it is used. With no filtering, this raises an error. However, we could alter the behaviour with

\msg_redirect_class:nn { error } { warning }

to turn all errors into warnings, or with

\msg_redirect_module:nnn { module } { error } { warning }
to alter only messages from that module, or even

\msg_redirect_name:nnn \{ module \} \{ my-message \} \{ warning \}

to target just one message. Redirection applies first to individual messages, then to messages from one module and finally to messages of one class. Thus it is possible to select out an individual message for special treatment even if the entire class is already redirected.

Multiple redirections are possible. Redirections can be cancelled by providing an empty argument for the target class. Redirection to a missing class raises an error immediately. Infinite loops are prevented by eliminating the redirection starting from the target of the redirection that caused the loop to appear. Namely, if redirections are requested as $A \rightarrow B$, $B \rightarrow C$ and $C \rightarrow A$ in this order, then the $A \rightarrow B$ redirection is cancelled.

\msg_redirect_class:nn \{ ⟨class one⟩ \} \{ ⟨class two⟩ \}

Changes the behaviour of messages of ⟨class one⟩ so that they are processed using the code for those of ⟨class two⟩.

\msg_redirect_module:nnn \{ ⟨module⟩ \} \{ ⟨class one⟩ \} \{ ⟨class two⟩ \}

Redirects message of ⟨class one⟩ for ⟨module⟩ to act as though they were from ⟨class two⟩. Messages of ⟨class one⟩ from sources other than ⟨module⟩ are not affected by this redirection. This function can be used to make some messages “silent” by default. For example, all of the warning messages of ⟨module⟩ could be turned off with:

\msg_redirect_module:nnn \{ module \} \{ warning \} \{ none \}

\msg_redirect_name:nnn \{ ⟨module⟩ \} \{ ⟨message⟩ \} \{ ⟨class⟩ \}

Redirects a specific ⟨message⟩ from a specific ⟨module⟩ to act as a member of ⟨class⟩ of messages. No further redirection is performed. This function can be used to make a selected message “silent” without changing global parameters:

\msg_redirect_name:nnn \{ module \} \{ annoying-message \} \{ none \}
Part XIX

The l3file package

File and I/O operations

This module provides functions for working with external files. Some of these functions apply to an entire file, and have prefix \file_, while others are used to work with files on a line by line basis and have prefix \ior_ (reading) or \iow_ (writing).

It is important to remember that when reading external files \TeX attempts to locate them using both the operating system path and entries in the \TeX file database (most \TeX systems use such a database). Thus the “current path” for \TeX is somewhat broader than that for other programs.

For functions which expect a ⟨file name⟩ argument, this argument may contain both literal items and expandable content, which should on full expansion be the desired file name. Active characters (as declared in \l_char_active_seq) are not expanded, allowing the direct use of these in file names. Quote tokens (") are not permitted in file names as they are reserved for internal use by some \TeX primitives.

Spaces are trimmed at the beginning and end of the file name: this reflects the fact that some file systems do not allow or interact unpredictably with spaces in these positions. When no extension is given, this will trim spaces from the start of the name only.

1 Input–output stream management

As \TeX engines have a limited number of input and output streams, direct use of the streams by the programmer is not supported in \L\TeX3. Instead, an internal pool of streams is maintained, and these are allocated and deallocated as needed by other modules. As a result, the programmer should close streams when they are no longer needed, to release them for other processes.

Note that I/O operations are global: streams should all be declared with global names and treated accordingly.

\ior_new:N \ior_new:c \iow_new:N \iow_new:c
\ior_open:Nn \ior_open:cn
\iow_open:Nn \iow_open:cn

\ior_new:N ⟨stream⟩
\ior_new:N ⟨stream⟩
\iow_new:N ⟨stream⟩
\iow_new:c

Globally reserves the name of the ⟨stream⟩, either for reading or for writing as appropriate. The ⟨stream⟩ is not opened until the appropriate \\..._open:Nn function is used. Attempting to use a ⟨stream⟩ which has not been opened is an error, and the ⟨stream⟩ will behave as the corresponding \c_term_....

\ior_open:Nn ⟨stream⟩ \⟨{file name}\⟩
\iow_open:cn

Opens ⟨file name⟩ for reading using ⟨stream⟩ as the control sequence for file access. If the ⟨stream⟩ was already open it is closed before the new operation begins. The ⟨stream⟩ is available for access immediately and will remain allocated to ⟨file name⟩ until a \ior_-close:N instruction is given or the \TeX run ends. If the file is not found, an error is raised.
\ior_open:NnTF
\ior_open:cnTF
New: 2013-01-12

\ior_open:Nn \ior_open:cn
Opens \textit{file name} for reading using \textit{stream} as the control sequence for file access. If the \textit{stream} was already open it is closed before the new operation begins. The \textit{stream} is available for access immediately and will remain allocated to \textit{file name} until a \ior_close:N instruction is given or the \TeX{} run ends. The \textit{true code} is then inserted into the input stream. If the file is not found, no error is raised and the \textit{false code} is inserted into the input stream.

\iow_open:Nn
\iow_open:cn
Updated: 2012-02-09

\iow_open:Nn \iow_open:cn
Opens \textit{file name} for writing using \textit{stream} as the control sequence for file access. If the \textit{stream} was already open it is closed before the new operation begins. The \textit{stream} is available for access immediately and will remain allocated to \textit{file name} until a \iow_close:N instruction is given or the \TeX{} run ends. Opening a file for writing clears any existing content in the file (i.e. writing is not additive).

\ior_show_list:
\ior_log_list:
\iow_show_list:
\iow_log_list:
New: 2017-06-27

Display (to the terminal or log file) a list of the file names associated with each open (read or write) stream. This is intended for tracking down problems.

1.1 Reading from files

Reading from files and reading from the terminal are separate processes in \texttt{expl3}. The functions \ior_get:NN and \ior_str_get:NN, and their branching equivalents, are designed to work with files.
Function that reads one or more lines (until an equal number of left and right braces are found) from the file input \langle stream \rangle and stores the result locally in the \langle token list variable \rangle variable. The material read from the \langle stream \rangle is tokenized by \TeX according to the category codes and \endlinechar in force when the function is used. Assuming normal settings, any lines which do not end in a comment character % have the line ending converted to a space, so for example input

\begin{verbatim}
a b c
\end{verbatim}

results in a token list a/b/c. Any blank line is converted to the token \par. Therefore, blank lines can be skipped by using a test such as

\begin{verbatim}
\ior_get:NN \l_my_stream \l_tmpa_tl
\tl_set:Nn \l_tmpb_tl { \par }
\tl_if_eq:NNF \l_tmpa_tl \l_tmpb_tl
...
\end{verbatim}

Also notice that if multiple lines are read to match braces then the resulting token list can contain \par tokens. In the non-branching version, where the \langle stream \rangle is not open the \langle tl var \rangle is set to \q_no_value.

\TeXhackers note: This protected macro is a wrapper around the \TeX primitive \readline. Regardless of settings, \TeX replaces trailing space and tab characters (character codes 32 and 9) in each line by an end-of-line character (character code \endlinechar, omitted if \endlinechar is negative or too large) before turning characters into tokens according to current category codes. With default settings, spaces appearing at the beginning of lines are also ignored.

Function that reads one line from the file input \langle stream \rangle and stores the result locally in the \langle token list variable \rangle variable. The material is read from the \langle stream \rangle as a series of tokens with category code 12 (other), with the exception of space characters which are given category code 10 (space). Multiple whitespace characters are retained by this process. It always only reads one line and any blank lines in the input result in the \langle token list variable \rangle being empty. Unlike \ior_get:NN, line ends do not receive any special treatment. Thus input

\begin{verbatim}
a b c
\end{verbatim}

results in a token list a \ b \ c with the letters a, b, and c having category code 12. In the non-branching version, where the \langle stream \rangle is not open the \langle tl var \rangle is set to \q_no_value.

\TeXhackers note: This protected macro is a wrapper around the \TeX primitive \readline. Regardless of settings, \TeX removes trailing space and tab characters (character codes 32 and 9). However, the end-line character normally added by this primitive is not included in the result of \ior_str_get:NN.

All mappings are done at the current group level, i.e. any local assignments made by the \langle function \rangle or \langle code \rangle discussed below remain in effect after the loop.
\ior_map_inline:Nn \ior_map_inline:Nn \ior_get:NN \ior_map_inline:Nn \ior_get:NN

Applies the \textit{inline function} to each set of \textit{lines} obtained by calling \texttt{\ior_get:NN} until reaching the end of the file. \TeX{} ignores any trailing new-line marker from the file it reads. The \textit{inline function} should consist of code which receives the \textit{line} as \texttt{#1}.

\ior_str_map_inline:Nn \ior_str_map_inline:Nn \ior_get:NN \ior_str_map_inline:Nn \ior_get:NN

Applies the \textit{inline function} to every \textit{line} in the \textit{stream}. The material is read from the \textit{stream} as a series of tokens with category code 12 (other), with the exception of space characters which are given category code 10 (space). The \textit{inline function} should consist of code which receives the \textit{line} as \texttt{#1}. Note that \TeX{} removes trailing space and tab characters (character codes 32 and 9) from every line upon input. \TeX{} also ignores any trailing new-line marker from the file it reads.

\ior_map_variable:NNn \ior_map_variable:NNn \ior_get:NN \ior_map_variable:NNn \ior_get:NN

For each set of \textit{lines} obtained by calling \texttt{\ior_get:NN} until reaching the end of the file, stores the \textit{lines} in the \textit{tl var} then applies the \textit{code}. The \textit{code} will usually make use of the \textit{variable}, but this is not enforced. The assignments to the \textit{variable} are local. Its value after the loop is the last set of \textit{lines}, or its original value if the \textit{stream} is empty. \TeX{} ignores any trailing new-line marker from the file it reads. This function is typically faster than \texttt{\ior_map_inline:Nn}.

\ior_str_map_variable:NNn \ior_str_map_variable:NNn \ior_get:NN \ior_str_map_variable:NNn \ior_get:NN

For each \textit{line} in the \textit{stream}, stores the \textit{line} in the \textit{variable} then applies the \textit{code}. The material is read from the \textit{stream} as a series of tokens with category code 12 (other), with the exception of space characters which are given category code 10 (space). The \textit{code} will usually make use of the \textit{variable}, but this is not enforced. The assignments to the \textit{variable} are local. Its value after the loop is the last \textit{line}, or its original value if the \textit{stream} is empty. Note that \TeX{} removes trailing space and tab characters (character codes 32 and 9) from every line upon input. \TeX{} also ignores any trailing new-line marker from the file it reads. This function is typically faster than \texttt{\ior_str_map_inline:Nn}.

\ior_map_break: \ior_map_break: \ior_get:NN \ior_map_break: \ior_get:NN

Used to terminate a \texttt{\ior_map...} function before all lines from the \textit{stream} have been processed. This normally takes place within a conditional statement, for example

\begin{verbatim}
\ior_map_inline:Nn \l_my_ior
{ \str_if_eq:nnTF { #1 } { bingo } { \ior_map_break: }
  \ior_map_break: }
\end{verbatim}

Use outside of a \texttt{\ior_map...} scenario leads to low level \TeX{} errors.

\TeX{}hackers note: When the mapping is broken, additional tokens may be inserted before further items are taken from the input stream. This depends on the design of the mapping function.

159
\ior_map_break:n \ior_map_break:n \{\langle code\rangle\}

Used to terminate a $\ior_map...$ function before all lines in the \langle stream\rangle have been processed, inserting the \langle code\rangle after the mapping has ended. This normally takes place within a conditional statement, for example

\ior_map_inline:Nn \l_my_ior
\{
  \str_if_eq:nnTF \{ #1 \} \{ bingo \}
  \{
    \ior_map_break:n \{ <code> \}
    \{
      \%
      \ Do something useful
    \}
  \}
\}

Use outside of a $\ior_map...$ scenario leads to low level \TeX{} errors.

$\TeX{}$hackers note: When the mapping is broken, additional tokens may be inserted before the \langle code\rangle is inserted into the input stream. This depends on the design of the mapping function.

\ior_if_eof_p:N \ior_if_eof_p:N \{\langle stream\rangle\}
\ior_if_eof:NTF \ior_if_eof:NTF \{\langle true code\rangle\} \{\langle false code\rangle\}

Tests if the end of a file \langle stream\rangle has been reached during a reading operation. The test also returns a true value if the \langle stream\rangle is not open.

1.2 Writing to files

\iow_now:Nn \iow_now:N\{\langle stream\rangle\} \{\langle tokens\rangle\}

This functions writes \langle tokens\rangle to the specified \langle stream\rangle immediately (i.e. the write operation is called on expansion of \iow_now:Nn).

\iow_log:n \iow_log:n \{\langle tokens\rangle\}

This function writes the given \langle tokens\rangle to the log (transcript) file immediately: it is a dedicated version of \iow_now:Nn.

\iow_term:n \iow_term:n \{\langle tokens\rangle\}

This function writes the given \langle tokens\rangle to the terminal file immediately: it is a dedicated version of \iow_now:Nn.
\io_shipout:Nn \io_shipout:(Nx|cn|cx)
\io_shipout:Nn \{\{tokens\}\}

This function writes \{tokens\} to the specified \{stream\} when the current page is finalised (i.e. at shipout). The x-type variants expand the \{tokens\} at the point where the function is used but not when the resulting tokens are written to the \{stream\} (cf. \io_shipout_x:Nn).

\TeXhackers note: When using expl3 with a format other than \ETeX, new line characters inserted using \io_newline: or using the line-wrapping code \io_wrap:nnN are not recognized in the argument of \io_shipout:Nn. This may lead to the insertion of additional unwanted line-breaks.

\io_shipout_x:Nn \io_shipout_x:(Nx|cn|cx)
\io_shipout_x:Nn \{\{tokens\}\}

This function writes \{tokens\} to the specified \{stream\} when the current page is finalised (i.e. at shipout). The \{tokens\} are expanded at the time of writing in addition to any expansion when the function is used. This makes these functions suitable for including material finalised during the page building process (such as the page number integer).

\TeXhackers note: This is a wrapper around the \TeX primitive \write. When using expl3 with a format other than \ETeX, new line characters inserted using \io_newline: or using the line-wrapping code \io_wrap:nnN are not recognized in the argument of \io_shipout:Nn. This may lead to the insertion of additional unwanted line-breaks.

\io_char:N
\io_char:N \langle char \rangle

Inserts \langle char \rangle into the output stream. Useful when trying to write difficult characters such as %, {, }, etc. in messages, for example:

\io_now:Nx \g_my_iow \{ \io_char:N \{ text \io_char:N \} \}

The function has no effect if writing is taking place without expansion (e.g. in the second argument of \io_now:Nn).

\io_newline:
\io_newline:

Function to add a new line within the \{tokens\} written to a file. The function has no effect if writing is taking place without expansion (e.g. in the second argument of \io_now:Nn).

\TeXhackers note: When using expl3 with a format other than \ETeX, the character inserted by \io_newline: is not recognized by \ETeX, which may lead to the insertion of additional unwanted line-breaks. This issue only affects \io_shipout:Nn, \io_shipout_x:Nn and direct uses of primitive operations.
1.3 Wrapping lines in output

\iow_wrap:nnnN \{\langle text\rangle\} \{\langle run-on text\rangle\} \{\langle set up\rangle\} \{\langle function\rangle\}

This function wraps the \langle text\rangle to a fixed number of characters per line. At the start of each line which is wrapped, the \langle run-on text\rangle is inserted. The line character count targeted is the value of \l_iow_line_count_int minus the number of characters in the \langle run-on text\rangle for all lines except the first, for which the target number of characters is simply \l_iow_line_count_int since there is no run-on text. The \langle text\rangle and \langle run-on text\rangle are exhaustively expanded by the function, with the following substitutions:

- \textbackslash\ or \iow_newline: may be used to force a new line,
- \textbackslash_: may be used to represent a forced space (for example after a control sequence),
- \#, \%, \{, \} may be used to represent the corresponding character,
- \iow_allow_break: may be used to allow a line-break without inserting a space (this is experimental),
- \iow_indent:n may be used to indent a part of the \langle text\rangle (not the \langle run-on text\rangle).

Additional functions may be added to the wrapping by using the \langle set up\rangle, which is executed before the wrapping takes place: this may include overriding the substitutions listed.

Any expandable material in the \langle text\rangle which is not to be expanded on wrapping should be converted to a string using \token_to_str:N, \tl_to_str:n, \tl_to_str:N, etc.

The result of the wrapping operation is passed as a braced argument to the \langle function\rangle, which is typically a wrapper around a write operation. The output of \iow_wrap:nnnN (i.e. the argument passed to the \langle function\rangle) consists of characters of category “other” (category code 12), with the exception of spaces which have category “space” (category code 10). This means that the output does not expand further when written to a file.

\TeXhackers note: Internally, \iow_wrap:nnnN carries out an x-type expansion on the \langle text\rangle to expand it. This is done in such a way that \exp_not:N or \exp_not:n could be used to prevent expansion of material. However, this is less conceptually clear than conversion to a string, which is therefore the supported method for handling expandable material in the \langle text\rangle.

\iow_indent:n \{\langle text\rangle\}

In the first argument of \iow_wrap:nnnN (for instance in messages), indents \langle text\rangle by four spaces. This function does not cause a line break, and only affects lines which start within the scope of the \langle text\rangle. In case the indented \langle text\rangle should appear on separate lines from the surrounding text, use \textbackslash\ to force line breaks.

\l_iow_line_count_int

The maximum number of characters in a line to be written by the \iow_wrap:nnnN function. This value depends on the \TeX system in use: the standard value is 78, which is typically correct for unmodified \TeXlive and \MiKTeX systems.
1.4 Constant input–output streams, and variables

\texttt{\gtmpa_iow} \quad \texttt{\gtmpb_iow} \quad \texttt{Rev: 2017-12-11}

Scratch input stream for global use. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

\texttt{\clog_iow} \quad \texttt{\ctermlow} \quad Constant output streams for writing to the log and to the terminal (plus the log), respectively.

\texttt{\gtmpa_iow} \quad \texttt{\gtmpb_iow} \quad \texttt{Rev: 2017-12-11}

Scratch output stream for global use. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

1.5 Primitive conditionals

\texttt{\ifdef:w} \quad \texttt{\if_eof:w \langle \text{stream} \rangle}
\quad \langle \text{true code} \rangle
\quad \texttt{\else:}
\quad \langle \text{false code} \rangle
\quad \texttt{\fi:}

Tests if the \langle \text{stream} \rangle returns “end of file”, which is true for non-existent files. The \texttt{\else:} branch is optional.

\textbf{\TeXhackers\,note:} This is the \TeX primitive \texttt{\ifeof}.

2 File operation functions

\texttt{\filecurrdir_str} \quad \texttt{\filecurrname_str} \quad \texttt{\filecurrext_str} \quad \texttt{Rev: 2017-06-21}

Contain the directory, name and extension of the current file. The directory is empty if the file was loaded without an explicit path (\textit{i.e.} if it is in the \TeX search path), and does \textit{not} end in \texttt{/} other than the case that it is exactly equal to the root directory. The \langle \text{name} \rangle and \langle \text{ext} \rangle parts together make up the file name, thus the \langle \text{name} \rangle part may be thought of as the “job name” for the current file. Note that \TeX does not provide information on the \langle \text{ext} \rangle part for the main (top level) file and that this file always has an empty \langle \text{dir} \rangle component. Also, the \langle \text{name} \rangle here will be equal to \texttt{\cystjobname_str}, which may be different from the real file name (if set using \texttt{--jobname}, for example).
Each entry is the path to a directory which should be searched when seeking a file. Each path can be relative or absolute, and should not include the trailing slash. The entries are not expanded when used so may contain active characters but should not feature any variable content. Spaces need not be quoted.

*TeX*hackers note: When working as a package in *L\!T\!E\!X* 2ε, expl3 will automatically append the current \input@path to the set of values from \l_file_search_path_seq.

\file_if_exist:nTF \{\langle file name\rangle\} \{\langle true code\rangle\} \{\langle false code\rangle\}

Searches for \langle file name\rangle using the current *L\!T\!E\!X* search path and the additional paths controlled by \l_file_search_path_seq.

\file_get:nnN \{\langle filename\rangle\} \{\langle setup\rangle\} \langle tl \rangle
\file_get:nnNTF \{\langle filename\rangle\} \{\langle setup\rangle\} \langle tl \rangle \{\langle true code\rangle\} \{\langle false code\rangle\}

Defines \langle tl \rangle to the contents of \langle filename\rangle. Category codes may need to be set appropriately via the \langle setup \rangle argument. The non-branching version sets the \langle tl \rangle to \texttt{q_no_value} if the file is not found. The branching version runs the \langle true code\rangle after the assignment to \langle tl \rangle if the file is found, and \langle false code\rangle otherwise.

\file_get_full_name:nN
\file_get_full_name:VN
\file_get_full_name:nNTF
\file_get_full_name:VNFT

Searches for \langle file name\rangle in the path as detailed for \file_if_exist:nTF, and if found sets the \langle tl var \rangle the fully-qualified name of the file, \textit{i.e.} the path and file name. This includes an extension \texttt{.tex} when the given \langle file name\rangle has no extension but the file found has that extension. In the non-branching version, the \langle tl var \rangle will be set to \texttt{q_no_value} in the case that the file does not exist.

\file_full_name:n \star
\file_full_name:V \star

Searches for \langle file name\rangle in the path as detailed for \file_if_exist:nTF, and if found leaves the fully-qualified name of the file, \textit{i.e.} the path and file name, in the input stream. This includes an extension \texttt{.tex} when the given \langle file name\rangle has no extension but the file found has that extension. If the file is not found on the path, the expansion is empty.
\file_parse_full_name:nNNN
\file_parse_full_name:VNNN

New: 2017-06-23
Updated: 2017-06-26

Parses the \textit{full name} and splits it into three parts, each of which is returned by setting the appropriate local string variable:

- The \textit{dir}: everything up to the last / (path separator) in the \textit{file path}. As with system \texttt{PATH} variables and related functions, the \textit{dir} does \textit{not} include the trailing / unless it points to the root directory. If there is no path (only a file name), \textit{dir} is empty.

- The \textit{name}: everything after the last / up to the last ., where both of those characters are optional. The \textit{name} may contain multiple . characters. It is empty if \textit{full name} consists only of a directory name.

- The \textit{ext}: everything after the last . (including the dot). The \textit{ext} is empty if there is no . after the last /.

This function does not expand the \textit{full name} before turning it to a string. It assume that the \textit{full name} either contains no quote (" characters or is surrounded by a pair of quotes.

\file_hex_dump:n
\file_hex_dump:nnn

New: 2019-11-19

Searches for \textit{file name} using the current \TeX{} search path and the additional paths controlled by \texttt{	extbackslash l_file_search_path_seq}. It then expands to leave the hexadecimal dump of the file content in the input stream. The file is read as bytes, which means that in contrast to most \TeX{} behaviour there will be a difference in result depending on the line endings used in text files. The same file will produce the same result between different engines: the algorithm used is the same in all cases. When the file is not found, the result of expansion is empty. The \texttt{\{start index\}} and \texttt{\{end index\}} values work as described for \texttt{\textbackslash str_range:nnn}.

\file_get_hex_dump:nN
\file_get_hex_dump:nNTF
\file_get_hex_dump:nnn
\file_get_hex_dump:nnnNTF

New: 2019-11-19

Sets the \texttt{\{tl var\}} to the result of applying \texttt{\textbackslash file_hex_dump:n/\textbackslash file_hex_dump:nnn} to the \texttt{\{file\}}. If the file is not found, the \texttt{\{tl var\}} will be set to \texttt{\textbackslash q_no_value}.

\file_mdfive_hash:n
\file_mdfive_hash:nnn

New: 2019-09-03

Searches for \textit{file name} using the current \TeX{} search path and the additional paths controlled by \texttt{\textbackslash l_file_search_path_seq}. It then expands to leave the MD5 sum generated from the contents of the file in the input stream. The file is read as bytes, which means that in contrast to most \TeX{} behaviour there will be a difference in result depending on the line endings used in text files. The same file will produce the same result between different engines: the algorithm used is the same in all cases. When the file is not found, the result of expansion is empty.

\file_get_mdfive_hash:nN
\file_get_mdfive_hash:nNTF

New: 2017-07-11
Updated: 2019-02-16

Sets the \texttt{\{tl var\}} to the result of applying \texttt{\textbackslash file_mdfive_hash:n/\textbackslash file_mdfive_hash:nnn} to the \texttt{\{file\}}. If the file is not found, the \texttt{\{tl var\}} will be set to \texttt{\textbackslash q_no_value}. 
\file_size:n \langle file name \rangle
\file_get_size:nN \langle file name \rangle \langle tl var \rangle
\file_timestamp:n \langle file name \rangle
\file_get_timestamp:nN \langle file name \rangle \langle tl var \rangle
\file_compare_timestamp:nNn \langle file-1 \rangle \langle comparator \rangle \langle file-2 \rangle \langle true code \rangle \langle false code \rangle
\file_input:n \langle file name \rangle
\file_compare_timestamp:nNnT { source-file } > { derived-file } 
\% Code to regenerate derived file

to work when the derived file is entirely absent. The timestamp of two absent files is regarded as different. This is not available in older versions of \LaTeXX.

\file_input:n \langle file name \rangle

Searches for \langle file name \rangle in the path as detailed for \file_if_exist:nTF, and if found reads in the file as additional \LaTeXX source. All files read are recorded for information and the file name stack is updated by this function. An error is raised if the file is not found.
\file_if_exist_input:n \file_if_exist_input:nF
\file_if_exist_input:nF \{\langle file name\rangle\} \{\langle false code\rangle\}

Searches for \langle file name\rangle using the current \TeX\ search path and the additional paths controlled by \file_path_include:n. If found then reads in the file as additional \LaTeX\ source as described for \file_input:n, otherwise inserts the \langle false code\rangle. Note that these functions do not raise an error if the file is not found, in contrast to \file_input:n.

\file_input_stop:
\file_input_stop:

Ends the reading of a file started by \file_input:n or similar before the end of the file is reached. Where the file reading is being terminated due to an error, \msg_-critical:nn(n) should be preferred.

\TeX\hackers note: This function must be used on a line on its own: \TeX\ reads files line-by-line and so any additional tokens in the “current” line will still be read.

This is also true if the function is hidden inside another function (which will be the normal case), i.e., all tokens on the same line in the source file are still processed. Putting it on a line by itself in the definition doesn’t help as it is the line where it is used that counts!

\file_show_list:
\file_log_list:

These functions list all files loaded by \LaTeX\ commands that populate \filelist or by \file_input:n. While \file_show_list: displays the list in the terminal, \file_log_list: outputs it to the log file only.
Part XX

The \texttt{l3skip} package

Dimensions and skips

\texttt{LATEX3} provides two general length variables: \texttt{dim} and \texttt{skip}. Lengths stored as \texttt{dim} variables have a fixed length, whereas \texttt{skip} lengths have a rubber (stretch/shrink) component. In addition, the \texttt{muskip} type is available for use in math mode: this is a special form of \texttt{skip} where the lengths involved are determined by the current math font (in \texttt{mu}). There are common features in the creation and setting of length variables, but for clarity the functions are grouped by variable type.

1 Creating and initialising \texttt{dim} variables

\begin{verbatim}
\dim_new:N \dim_new:c
\dim_new:NTF \dim_new:CF
\end{verbatim}

Creates a new \texttt{(dimension)} or raises an error if the name is already taken. The declaration is global. The \texttt{(dimension)} is initially equal to 0 pt.

\begin{verbatim}
\dim_const:Nn \dim_const:cn
\end{verbatim}

Creates a new constant \texttt{(dimension)} or raises an error if the name is already taken. The value of the \texttt{(dimension)} is set globally to the \texttt{(dimension expression)}.

\begin{verbatim}
\dim_zero:N \dim_zero:c \dim_gzero:N \dim_gzero:c
\end{verbatim}

Sets \texttt{(dimension)} to 0 pt.

\begin{verbatim}
\dim_zero_new:N \dim_zero_new:c \dim_gzero_new:N \dim_gzero_new:c
\end{verbatim}

Ensures that the \texttt{(dimension)} exists globally by applying \texttt{\dim_new:N} if necessary, then applies \texttt{\dim_(g)zero:N} to leave the \texttt{(dimension)} set to zero.

\begin{verbatim}
\dim_if_exist_p:N \dim_if_exist_p:cn \dim_if_exist:NTF \dim_if_exist:CF
\end{verbatim}

Tests whether the \texttt{(dimension)} is currently defined. This does not check that the \texttt{(dimension)} really is a dimension variable.
2 Setting \texttt{dim} variables

\begin{itemize}
\item \texttt{\dim_add:Nn \langle \textit{dimension} \rangle \{\langle \textit{dimension expression} \rangle\}}
\begin{flushleft}
Adds the result of the \textit{\langle dimension expression \rangle} to the current content of the \textit{\langle dimension \rangle}.
\end{flushleft}
\item \texttt{\dim_add:cn}
\item \texttt{\dim_gadd:Nn}
\item \texttt{\dim_gadd:cn}
\end{itemize}

\textit{Updated: 2011-10-22}

\begin{itemize}
\item \texttt{\dim_set:Nn \langle \textit{dimension} \rangle \{\langle \textit{dimension expression} \rangle\}}
\begin{flushleft}
Sets \textit{\langle dimension \rangle} to the value of \textit{\langle dimension expression \rangle}, which must evaluate to a length with units.
\end{flushleft}
\item \texttt{\dim_set:cn}
\item \texttt{\dim_gset:Nn}
\item \texttt{\dim_gset:cn}
\end{itemize}

\textit{Updated: 2011-10-22}

\begin{itemize}
\item \texttt{\dim_set_eq:NN \langle \textit{dimension 1} \rangle \langle \textit{dimension 2} \rangle}
\begin{flushleft}
Sets the content of \textit{\langle dimension 1 \rangle} equal to that of \textit{\langle dimension 2 \rangle}.
\end{flushleft}
\item \texttt{\dim_set_eq:NN (cN|Nc|cc)}
\item \texttt{\dim_gset_eq:NN (cN|Nc|cc)}
\end{itemize}

\textit{Updated: 2011-10-22}

\begin{itemize}
\item \texttt{\dim_sub:Nn \langle \textit{dimension} \rangle \{\langle \textit{dimension expression} \rangle\}}
\begin{flushleft}
Subtracts the result of the \textit{\langle dimension expression \rangle} from the current content of the \textit{\langle dimension \rangle}.
\end{flushleft}
\item \texttt{\dim_sub:cn}
\item \texttt{\dim_gsub:Nn}
\item \texttt{\dim_gsub:cn}
\end{itemize}

\textit{Updated: 2011-10-22}

3 Utilities for dimension calculations

\begin{itemize}
\item \texttt{\dim_abs:n \{\langle \textit{dimexpr} \rangle\}}
\begin{flushleft}
Converts the \textit{\langle dimexpr \rangle} to its absolute value, leaving the result in the input stream as a \textit{\langle dimension denotation \rangle}.
\end{flushleft}
\item \texttt{\dim_max:nn \{\langle \textit{dimexpr} 1 \rangle\} \{\langle \textit{dimexpr} 2 \rangle\}}
\item \texttt{\dim_min:nn \{\langle \textit{dimexpr} 1 \rangle\} \{\langle \textit{dimexpr} 2 \rangle\}}
\end{itemize}

\textit{New: 2012-09-09}

\textit{Updated: 2012-09-26}

Evaluates the two \textit{\langle dimension expressions \rangle} and leaves either the maximum or minimum value in the input stream as appropriate, as a \textit{\langle dimension denotation \rangle}. 

169
\dim_ratio:nn \dim_ratio:nn \{\dimexpr1\}\{\dimexpr2\}

Parses the two \langle dimension expressions \rangle and converts the ratio of the two to a form suitable for use inside a \langle dimension expression \rangle. This ratio is then left in the input stream, allowing syntax such as

\dim_set:Nn \l_my_dim
\{ 10 \text{ pt} * \dim_ratio:nn \{ 5 \text{ pt} \} \{ 10 \text{ pt} \} \}

The output of \dim_ratio:nn on full expansion is a ratio expression between two integers, with all distances converted to scaled points. Thus

\tl_set:Nx \l_my_tl \{ \dim_ratio:nn \{ 5 \text{ pt} \} \{ 10 \text{ pt} \} \}
\tl_show:N \l_my_tl

displays 327680/655360 on the terminal.

4 Dimension expression conditionals

\dim_compare_p:nNn \dim_compare_p:nNn \{\dimexpr1\} \langle relatio\rangle \{\dimexpr2\}
\dim_compare:nNnTF
\{\dimexpr1\} \langle relatio\rangle \{\dimexpr2\}
\{\langle true code\rangle\} \{\langle false code\rangle\}

This function first evaluates each of the \langle dimension expressions \rangle as described for \dim_minus:eval:n. The two results are then compared using the \langle relatio\rangle:

Equal =
Greater than >
Less than <

This function is less flexible than \dim_compare:nTF but around 5 times faster.
This function evaluates the \textit{dimension expressions} as described for ~\texttt{\textbackslash dim\_eval:n}~ and compares consecutive result using the corresponding \textit{relations}, namely it compares \langle \textit{dimexpr}_1 \rangle \text{ and } \langle \textit{dimexpr}_2 \rangle \text{ using the } \langle \textit{relation}_1 \rangle, \text{ then } \langle \textit{dimexpr}_2 \rangle \text{ and } \langle \textit{dimexpr}_3 \rangle \text{ using the } \langle \textit{relation}_2 \rangle, \text{ until finally comparing } \langle \textit{dimexpr}_N \rangle \text{ and } \langle \textit{dimexpr}_{N+1} \rangle \text{ using the } \langle \textit{relation}_N \rangle. \text{ The test yields } \texttt{true} \text{ if all comparisons are } \texttt{true}. \text{ Each } \langle \textit{dimension expression} \rangle \text{ is evaluated only once, and the evaluation is lazy, in the sense that if one comparison is } \texttt{false}, \text{ then no other } \langle \textit{dimension expression} \rangle \text{ is evaluated and no other comparison is performed. The } \langle \textit{relations} \rangle \text{ can be any of the following:}

\begin{align*}
\text{Equal} & \quad = \quad \text{or} \quad == \\
\text{Greater than or equal to} & \quad >= \\
\text{Greater than} & \quad > \\
\text{Less than or equal to} & \quad <= \\
\text{Less than} & \quad < \\
\text{Not equal} & \quad !=
\end{align*}

\text{This function is more flexible than } \texttt{\textbackslash dim\_compare:nNnTF} \text{ but around 5 times slower.
This function evaluates the \textit{(test dimension expression)} and compares this in turn to each of the \textit{(dimension expression cases)}. If the two are equal then the associated \textit{(code)} is left in the input stream and other cases are discarded. If any of the cases are matched, the \textit{(true code)} is also inserted into the input stream (after the code for the appropriate case), while if none match then the \textit{(false code)} is inserted. The function \texttt{\dim_case:nN}, which does nothing if there is no match, is also available. For example

\begin{verbatim}
\dim_set:Nn \l_tmpa_dim { 5 pt }
\dim_case:nF { 2 \l_tmpa_dim }
{ 5 pt }  \{ Small \}
{ 4 pt + 6 pt } \{ Medium \}
{ - 10 pt } \{ Negative \}
{ No idea! }
\end{verbatim}

leaves “Medium” in the input stream.

5 Dimension expression loops

\begin{verbatim}
\dim_do_until:nNnn \dim_do_until:nNnn \dim_until_do:nNnn \dim_until_do:nNnn
\end{verbatim}
6 Dimension step functions

This function first evaluates the \textit{initial value}, \textit{step} and \textit{final value}, all of which should be dimension expressions. Then for each \textit{value} from the \textit{initial value} to the \textit{final value} in turn (using \textit{step} between each \textit{value}), the \textit{code} is inserted into the input stream with \texttt{#1} replaced by the current \textit{value}. Thus the \textit{code} should define a function of one argument (#1).
This function first evaluates the ⟨initial value⟩, ⟨step⟩ and ⟨final value⟩, all of which should be dimension expressions. Then for each ⟨value⟩ from the ⟨initial value⟩ to the ⟨final value⟩ in turn (using ⟨step⟩ between each ⟨value⟩), the ⟨code⟩ is inserted into the input stream, with the ⟨tl var⟩ defined as the current ⟨value⟩. Thus the ⟨code⟩ should make use of the ⟨tl var⟩.

7 Using dim expressions and variables

\dim_step_variable:nnnNn

\{⟨initial value⟩\} \{⟨step⟩\} \{⟨final value⟩\} \{tl var\} \{⟨code⟩\}

\dim_eval:n \{⟨dimension expression⟩\}

Evaluates the ⟨dimension expression⟩, expanding any dimensions and token list variables within the ⟨expression⟩ to their content (without requiring \dim_use:N/\tl_use:N) and applying the standard mathematical rules. The result of the calculation is left in the input stream as a ⟨dimension denotation⟩ after two expansions. This is expressed in points (pt), and requires suitable termination if used in a \TeX-style assignment as it is not an ⟨internal dimension⟩.

\dim_sign:n \{⟨dimexpr⟩\}

Evaluates the ⟨dimexpr⟩ then leaves 1 or 0 or −1 in the input stream according to the sign of the result.

\dim_use:N \langle dimension⟩
\dim_use:c \langle dimension⟩

ReCOVERs the content of a ⟨dimension⟩ and places it directly in the input stream. An error is raised if the variable does not exist or if it is invalid. Can be omitted in places where a ⟨dimension⟩ is required (such as in the argument of \dim_eval:n).

\TeXhackers note: \dim_use:N is the \TeX primitive \the: this is one of several \LaTeX names for this primitive.

\dim_to_decimal:n \{⟨dimexpr⟩\}

Evaluates the ⟨dimension expression⟩, and leaves the result, expressed in points (pt) in the input stream, with no units. The result is rounded by \TeX to four or five decimal places. If the decimal part of the result is zero, it is omitted, together with the decimal marker.

For example

\dim_to_decimal:n \{1bp\}

leaves 1.00374 in the input stream, i.e. the magnitude of one “big point” when converted to \TeX points.
\dim_to_decimal_in_bp:n \{ \langle \text{dimexpr} \rangle \} \\
New: 2014-07-15

Evaluates the \langle \text{dimension expression} \rangle, and leaves the result, expressed in big points (bp) in the input stream, with \textit{no units}. The result is rounded by \TeX to four or five decimal places. If the decimal part of the result is zero, it is omitted, together with the decimal marker.

For example

\dim_to_decimal_in_bp:n \{ 1pt \}

leaves 0.99628 in the input stream, i.e. the magnitude of one (\TeX) point when converted to big points.

\dim_to_decimal_in_sp:n \{ \langle \text{dimexpr} \rangle \} \\
New: 2015-05-18

Evaluates the \langle \text{dimension expression} \rangle, and leaves the result, expressed in scaled points (sp) in the input stream, with \textit{no units}. The result is necessarily an integer.

\dim_to_decimal_in_unit:nn \{ \langle \text{dimexpr} \rangle \} \{ \langle \text{dimexpr} \rangle \} \\
New: 2014-07-15

Evaluates the \langle \text{dimension expressions} \rangle, and leaves the value of \langle \text{dimexpr}_1 \rangle, expressed in a unit given by \langle \text{dimexpr}_2 \rangle, in the input stream. The result is a decimal number, rounded by \TeX to four or five decimal places. If the decimal part of the result is zero, it is omitted, together with the decimal marker.

For example

\dim_to_decimal_in_unit:nn \{ 1bp \} \{ 1mm \}

leaves 0.35277 in the input stream, i.e. the magnitude of one big point when converted to millimetres.

Note that this function is not optimised for any particular output and as such may give different results to \dim_to_decimal_in_bp:n or \dim_to_decimal_in_sp:n. In particular, the latter is able to take a wider range of input values as it is not limited by the ability to calculate a ratio using \varepsilon-\TeX primitives, which is required internally by \dim_to_decimal_in_unit:nn.

\dim_to_fp:n \{ \langle \text{dimexpr} \rangle \} \\
New: 2012-05-08

Expands to an internal floating point number equal to the value of the \langle \text{dimexpr} \rangle in pt. Since dimension expressions are evaluated much faster than their floating point equivalent, \dim_to_fp:n can be used to speed up parts of a computation where a low precision and a smaller range are acceptable.

8 Viewing dim variables

\dim_show:N \{ \langle \text{dimension} \rangle \}

Displays the value of the \langle \text{dimension} \rangle on the terminal.
\dim_show:n \{\langle\text{dimension expression}\rangle}\}

Displays the result of evaluating the \langle\text{dimension expression}\rangle on the terminal.

\dim_log:N \dim_log:c
\{\langle\text{dimension}\rangle\}

Writes the value of the \langle\text{dimension}\rangle in the log file.

\dim_log:n \{\langle\text{dimension expression}\rangle\}

Writes the result of evaluating the \langle\text{dimension expression}\rangle in the log file.

9 Constant dimensions

\c_max_dim

The maximum value that can be stored as a dimension. This can also be used as a component of a skip.

\c_zero_dim

A zero length as a dimension. This can also be used as a component of a skip.

10 Scratch dimensions

\l_tmpa_dim \l_tmpb_dim

Scratch dimension for local assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

\g_tmpa_dim \g_tmpb_dim

Scratch dimension for global assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

11 Creating and initialising skip variables

\skip_new:N \skip_new:c
\{\langle\text{skip}\rangle\}

Creates a new \langle\text{skip}\rangle or raises an error if the name is already taken. The declaration is global. The \langle\text{skip}\rangle is initially equal to 0pt.
\skip_const:Nn \skip_const:cn

New: 2012-03-05

\skip_const:Nn \skip_const:cn \skip_expression

Creates a new constant \skip{} or raises an error if the name is already taken. The value of the \skip{} is set globally to the \skip_expression.

\skip_zero:N \skip_zero:c \skip_gzero:N \skip_gzero:c

\skip_zero_new:N \skip_zero_new:c \skip_gzero_new:N \skip_gzero_new:c

New: 2012-03-05

\skip_zero:N \skip_zero:c \skip_gzero:N \skip_gzero:c

Ensures that the \skip{} exists globally by applying \skip_new:N if necessary, then applies \skip_(g)zero:N to leave the \skip{} set to zero.

\skip_zero_new:N \skip_zero_new:c \skip_gzero_new:N \skip_gzero_new:c

13 Skip expression conditionals

\skip_if_eq_p:nn \skip_if_eq_p:nn \skip_if_eq_p:nn \skip_if_eq_p:nn \skip_if_eq:nnTF \skip_if_eq:nnTF \skip_if_eq:nnTF

\skip_if_finite_p:n \skip_if_finite_p:n \skip_if_finite_p:n
\skip_if_finite:nTF \skip_if_finite:nTF \skip_if_finite:nTF

This function first evaluates each of the \langle skip expressions \rangle as described for \skip_eval:n. The two results are then compared for exact equality, \textit{i.e.} both the fixed and rubber components must be the same for the test to be true.

\skip_if_finite_p:n \skip_if_finite:nTF
\skip_if_finite:p:n \skip_if_finite:nTF

Evaluates the \langle skip expression \rangle as described for \skip_eval:n, and then tests if all of its components are finite.

14 Using skip expressions and variables

\skip_eval:n \skip_eval:n \skip_eval:n \skip_eval:n

Evaluates the \langle skip expression \rangle, expanding any skips and token list variables within the \langle expression \rangle to their content (without requiring \skip_use:N/\tl_use:N) and applying the standard mathematical rules. The result of the calculation is left in the input stream as a \langle glue denotation \rangle after two expansions. This is expressed in points (pt), and requires suitable termination if used in a \TeX-style assignment as it is not an \langle internal glue \rangle.

\skip_use:N \skip_use:N \skip_use:N \skip_use:N

Recovers the content of a \langle skip \rangle and places it directly in the input stream. An error is raised if the variable does not exist or if it is invalid. Can be omitted in places where a \langle dimension \rangle or \langle skip \rangle is required (such as in the argument of \skip_eval:n).

\TeXhackers note: \skip_use:N is the \TeX primitive \texttt{\the}: this is one of several \TeX3 names for this primitive.

15 Viewing skip variables

\skip_show:N \skip_show:N \skip_show:N \skip_show:N \skip_show:n \skip_show:n \skip_show:n

Displays the value of the \langle skip \rangle on the terminal.

Displays the result of evaluating the \langle skip expression \rangle on the terminal.

\g_tmpa_skip \g_tmpb_skip

\skip_horizontal:N \skip_horizontal:c \skip_horizontal:n
Updated: 2011-10-22

\texttt{\TeX} hackers note: \skip_horizontal:N is the \TeX primitive \hskip renamed.

16 Constant skips

\c_max_skip
The maximum value that can be stored as a skip (equal to \c_max_dim in length), with no stretch nor shrink component.

\c_zero_skip
A zero length as a skip, with no stretch nor shrink component.

17 Scratch skips

\l_tmpa_skip \l_tmpb_skip
Scratch skip for local assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

\g_tmpa_skip \g_tmpb_skip
Scratch skip for global assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

18 Inserting skips into the output

\skip_horizontal:N \skip_horizontal:c \skip_horizontal:n
Inserts a horizontal \langle \textit{skip} \rangle into the current list. The argument can also be a \langle \textit{dim} \rangle.
\skip_vertical:N \skip_vertical:c \skip_vertical:n  
Updated: 2011-10-22

\skip_vertical:N \skip \skip_vertical:n \{\skipexpr\}
Inserts a vertical \textit{skip} into the current list. The argument can also be a \textit{dim}.

\TeXhackers\note: \skip_vertical:N is the \TeX\ primitive \skip renamed.

19 Creating and initialising \textit{muskip} variables

\muskip_new:N \muskip_new:c
Creates a new \textit{muskip} or raises an error if the name is already taken. The declaration is global. The \textit{muskip} is initially equal to 0\mu.

\muskip_const:Nn \muskip_const:cn
Creates a new constant \textit{muskip} or raises an error if the name is already taken. The value of the \textit{muskip} is set globally to the \textit{muskip expression}.

\skip_zero:N \skip:c \skip:n
\muskip_zero:N \muskip_zero:c \muskip_gzero:N \muskip_gzero:c
Sets \textit{muskip} to 0\mu.

\muskip_zero_new:N \muskip_zero_new:c \muskip_gzero_new:N \muskip_gzero_new:c
Ensures that the \textit{muskip} exists globally by applying \muskip_new:N if necessary, then applies \muskip_(g)zero:N to leave the \textit{muskip} set to zero.

\muskip_if_exist_p:N \muskip_if_exist_p:c \muskip_if_exist:NTF \muskip_if_exist:CTF
Tests whether the \textit{muskip} is currently defined. This does not check that the \textit{muskip} really is a muskip variable.

20 Setting \textit{muskip} variables

\muskip_add:Nn \muskip_add:cn \muskip_gadd:Nn \muskip_gadd:cn
Adds the result of the \textit{muskip expression} to the current content of the \textit{muskip}.
Sets \texttt{\textbackslash{miskip}} to the value of \texttt{\textbackslash{miskip expression}}), which must evaluate to a math length with units and may include a rubber component (for example 1 mu plus 0.5 mu).

\texttt{\textbackslash{miskip_set:Nn}} \texttt{\textbackslash{miskip_set:cn}} \texttt{\textbackslash{miskip_gset:Nn}} \texttt{\textbackslash{miskip_gset:cn}}

Updated: 2011-10-22

Sets the content of \texttt{\textbackslash{miskip}} to that of \texttt{\textbackslash{miskip}}.

\texttt{\textbackslash{miskip_set_eq:NN}} \texttt{\textbackslash{miskip_set_eq:cn}} \texttt{\textbackslash{miskip_gset_eq:NN}} \texttt{\textbackslash{miskip_gset_eq:cn}}

Updated: 2011-10-22

Subtracts the result of the \texttt{\textbackslash{miskip expression}} from the current content of the \texttt{\textbackslash{miskip}}.

\texttt{\textbackslash{miskip_sub:Nn}} \texttt{\textbackslash{miskip_sub:cn}} \texttt{\textbackslash{miskip_gsub:Nn}} \texttt{\textbackslash{miskip_gsub:cn}}

Updated: 2011-10-22

21 Using \texttt{miskip} expressions and variables

\texttt{\textbackslash{miskip_eval:n}} \texttt{\textbackslash{miskip_eval:cn}}

Updated: 2011-10-22

Evaluates the \texttt{\textbackslash{miskip expression}}, expanding any skips and token list variables within the \texttt{\textbackslash{expression}} to their content (without requiring \texttt{\textbackslash{miskip_use:N}}/\texttt{\tl_use:N}) and applying the standard mathematical rules. The result of the calculation is left in the input stream as a \texttt{\textbackslash{muglue denotation}} after two expansions. This is expressed in mu, and requires suitable termination if used in a \TeX-style assignment as it is not an \texttt{\textbackslash{internal muglue}}.

\texttt{\textbackslash{miskip_use:N}} \texttt{\textbackslash{miskip_use:c}}

Recovers the content of a \texttt{\textbackslash{skip}} and places it directly in the input stream. An error is raised if the variable does not exist or if it is invalid. Can be omitted in places where a \texttt{\textbackslash{dimension}} is required (such as in the argument of \texttt{\textbackslash{miskip_eval:n}}).

\TeXhackers note: \texttt{\textbackslash{miskip_use:N}} is the \TeX primitive \texttt{\the:} this is one of several \TeX{} names for this primitive.

22 Viewing \texttt{miskip} variables

\texttt{\textbackslash{miskip_show:N}} \texttt{\textbackslash{miskip_show:cn}}

Displays the value of the \texttt{\textbackslash{miskip}} on the terminal.

\texttt{\textbackslash muskip\_show:n} \hspace{1cm} \texttt{\textbackslash muskip\_show:n \{\textit{muskip expression}\}}

Displays the result of evaluating the \textit{\textit{muskip expression}} on the terminal.

\texttt{\textbackslash muskip\_log:N} \hspace{1cm} \texttt{\textbackslash muskip\_log:N \{\textit{muskip}\}}

 Writes the value of the \textit{\textit{muskip}} in the log file.

\texttt{\textbackslash muskip\_log:n} \hspace{1cm} \texttt{\textbackslash muskip\_log:n \{\textit{muskip expression}\}}

 Writes the result of evaluating the \textit{\textit{muskip expression}} in the log file.

\section*{23 Constant muskips}

\texttt{\textbackslash c\_max\_muskip}

The maximum value that can be stored as a muskip, with no stretch nor shrink component.

\texttt{\textbackslash c\_zero\_muskip}

A zero length as a muskip, with no stretch nor shrink component.

\section*{24 Scratch muskips}

\texttt{\textbackslash l\_tmpa\_muskip} \hspace{1cm} \texttt{\textbackslash l\_tmpb\_muskip}

Scratch muskip for local assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

\texttt{\textbackslash g\_tmpa\_muskip} \hspace{1cm} \texttt{\textbackslash g\_tmpb\_muskip}

Scratch muskip for global assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

\section*{25 Primitive conditional}

\texttt{\textbackslash if\_dim:w \*} \hspace{1cm} \texttt{\textbackslash if\_dim:w \{\textit{dimen}_1\} \{\textit{relation}\} \{\textit{dimen}_2\} \{\textit{true code}\} \texttt{\textbackslash else:} \texttt{\{\textit{false}\} \texttt{\textbackslash fi:}}

Compare two dimensions. The \textit{\textit{relation}} is one of \texttt{<}, \texttt{=} or \texttt{>} with category code 12.

\textbf{\LaTeX3hackers note:} This is the \LaTeX primitive \texttt{\textbackslash ifdim}. 

182
The \texttt{l3keys} package

Key–value interfaces

The key–value method is a popular system for creating large numbers of settings for controlling function or package behaviour. The system normally results in input of the form

\begin{verbatim}
\MyModuleSetup{
  key-one = value one,
  key-two = value two
}
\end{verbatim}

or

\begin{verbatim}
\MyModuleMacro[
  key-one = value one,
  key-two = value two
]{argument}
\end{verbatim}

for the user.

The high level functions here are intended as a method to create key–value controls. Keys are themselves created using a key–value interface, minimising the number of functions and arguments required. Each key is created by setting one or more \textit{properties} of the key:

\begin{verbatim}
\keys_define:nn { mymodule }
  {
    key-one .code:n = code including parameter #1,
    key-two .tl_set:N = \l_mymodule_store_tl
  }
\end{verbatim}

These values can then be set as with other key–value approaches:

\begin{verbatim}
\keys_set:nn { mymodule }
  {
    key-one = value one,
    key-two = value two
  }
\end{verbatim}

At a document level, \texttt{\keys_set:nn} is used within a document function, for example

\begin{verbatim}
\DeclareDocumentCommand \MyModuleSetup { m }{ \keys_set:nn { mymodule } { #1 } }
\DeclareDocumentCommand \MyModuleMacro { o m }{ \group_begin:
  \keys_set:nn { mymodule } { #1 }
  % Main code for \MyModuleMacro
  \group_end:
}
\end{verbatim}
Key names may contain any tokens, as they are handled internally using \texttt{tl_to_str:n}. As discussed in section 2, it is suggested that the character / is reserved for sub-division of keys into logical groups. Functions and variables are \textit{not} expanded when creating key names, and so

\begin{verbatim}
\tl_set:Nn \l_mymodule_tmp_tl { key }
\keys_define:nn { mymodule }
{ \l_mymodule_tmp_tl .code:n = code }
\end{verbatim}

creates a key called \l_mymodule_tmp_tl, and not one called key.

\section{Creating keys}

\begin{verbatim}
\keys_define:nn \{module\} \{keyval list\}
\end{verbatim}

Parses the \texttt{\{keyval list\}} and defines the keys listed there for \texttt{\{module\}}. The \texttt{\{module\}} name is treated as a string. In practice the \texttt{\{module\}} should be chosen to be unique to the module in question (unless deliberately adding keys to an existing module).

The \texttt{\{keyval list\}} should consist of one or more key names along with an associated key \textit{property}. The properties of a key determine how it acts. The individual properties are described in the following text; a typical use of \texttt{\keys_define:nn} might read

\begin{verbatim}
\keys_define:nn { mymodule }
{ keyname .code:n = Some-code-using-\#1,
  keyname .value_required:n = true }
\end{verbatim}

where the properties of the key begin from the . after the key name.

The various properties available take either no arguments at all, or require one or more arguments. This is indicated in the name of the property using an argument specification. In the following discussion, each property is illustrated attached to an arbitrary \texttt{\{key\}}, which when used may be supplied with a \texttt{\{value\}}. All key definitions are local.

Key properties are applied in the reading order and so the ordering is significant. Key properties which define “actions”, such as \texttt{.code:n}, \texttt{.tl_set:N}, etc., override one another. Some other properties are mutually exclusive, notably \texttt{.value_required:n} and \texttt{.value_forbidden:n}, and so they replace one another. However, properties covering non-exclusive behaviours may be given in any order. Thus for example the following definitions are equivalent.

\begin{verbatim}
\keys_define:nn { mymodule }
{ keyname .code:n = Some-code-using-\#1,
  keyname .value_required:n = true }
\keys_define:nn { mymodule }
{ }
\end{verbatim}

184
keyname.value_required:n = true,
keyname.code:n = Some-code-using-#1
}

Note that with the exception of the special .undefine: property, all key properties define the key within the current TeX scope.

(key).bool_set:N = (boolean)
Defines (key) to set (boolean) to (value) (which must be either true or false). If the variable does not exist, it will be created globally at the point that the key is set up.

(key).bool_set_inverse:N = (boolean)
Defines (key) to set (boolean) to the logical inverse of (value) (which must be either true or false). If the (boolean) does not exist, it will be created globally at the point that the key is set up.

(key).choice: Sets (key) to act as a choice key. Each valid choice for (key) must then be created, as discussed in section 3.

(key).choices:nn = {(choices)} {(code)}
Sets (key) to act as a choice key, and defines a series (choices) which are implemented using the (code). Inside (code), \l_keys_choice_tl will be the name of the choice made, and \l_keys_choice_int will be the position of the choice in the list of (choices) (indexed from 1). Choices are discussed in detail in section 3.

(key).clist_set:N = (comma list variable)
Defines (key) to set (comma list variable) to (value). Spaces around commas and empty items will be stripped. If the variable does not exist, it is created globally at the point that the key is set up.

(key).code:n = {(code)}
Stores the (code) for execution when (key) is used. The (code) can include one parameter (#1), which will be the (value) given for the (key).

(key).cs_set:Np = (control sequence) (arg. spec.)
Defines (key) to set (control sequence) to have (arg. spec.) and replacement text (value).
\keys_define:nn { mymodule }
{  
  key .code:n = Hello-#1,  
  key .default:n = World  
}
\keys_set:nn { mymodule }
{  
  key = Fred, % Prints 'Hello Fred'
  key, % Prints 'Hello World'
  key = , % Prints 'Hello ' 
}

The default does not affect keys where values are required or forbidden. Thus a required value cannot be supplied by a default value, and giving a default value for a key which cannot take a value does not trigger an error.

\keys_define:nn { mymodule }
{  
  key .dim_set:N = \dim_set:N  
}
\keys_set:nn { mymodule }
{  
  key = Fred, % Prints 'Hello Fred'
  key, % Prints 'Hello World'
  key = , % Prints 'Hello ' 
}

\keys_define:nn { mymodule }
{  
  key .fp_set:N = \fp_set:N  
}
\keys_set:nn { mymodule }
{  
  key = Fred, % Prints 'Hello Fred'
  key, % Prints 'Hello World'
  key = , % Prints 'Hello ' 
}

\keys_define:nn { mymodule }
{  
  key .inherit:n = \inherit:n  
}
\keys_set:nn { mymodule }
{  
  key = Fred, % Prints 'Hello Fred'
  key, % Prints 'Hello World'
  key = , % Prints 'Hello ' 
}

Updated: 2016-11-22
\initial:n \(\text{.initial:n = \{\text{value}\}}\)

Initialises the \(\text{.initial:n}\) with the \(\text{.initial:n}\), equivalent to

\keys_set:nn \(\{\text{module}\}\) \{ \text{.initial:n} \}

\int_set:N \(\text{.int_set:N = \{\text{integer}\}}\)

Defines \(\text{.int_set:N}\) to set \(\text{.int_set:N}\) to \(\text{.int_set:N}\) (which must be an integer expression). If the variable does not exist, it is created globally at the point that the key is set up. The key will require a value at point-of-use unless a default is set.

\meta:n \(\text{.meta:n = \{\text{keyval list}\}}\)

Makes \(\text{.meta:n}\) a meta-key, which will set \(\text{.meta:n}\) in one go. The \(\text{.meta:n}\) can refer as \#1 to the value given at the time the \(\text{.meta:n}\) is used (or, if no value is given, the \(\text{.meta:n}\)’s default value).

\meta:nn \(\text{.meta:nn = \{\text{path}\} \{\text{keyval list}\}}\)

Makes \(\text{.meta:nn}\) a meta-key, which will set \(\text{.meta:nn}\) in one go using the \(\text{.meta:nn}\) in place of the current one. The \(\text{.meta:nn}\) can refer as \#1 to the value given at the time the \(\text{.meta:nn}\) is used (or, if no value is given, the \(\text{.meta:nn}\)’s default value).

\multichoice: \(\text{.multichoice:}\)

Sets \(\text{.multichoice:}\) to act as a multiple choice key. Each valid choice for \(\text{.multichoice:}\) must then be created, as discussed in section 3.

\multichoice:nn \(\text{.multichoice:nn = \{\text{choices}\} \{\text{code}\}}\)

Sets \(\text{.multichoice:nn}\) to act as a multiple choice key, and defines a series \(\text{.multichoice:nn}\) which are implemented using the \(\text{.multichoice:nn}\). Inside \(\text{.multichoice:nn}\), \l_keys_choice_tl \text{will be the name of the choice made, and } \l_keys_choice_int \text{ will be the position of the choice in the list of \text{.multichoice:nn}} \text{(indexed from 1). Choices are discussed in detail in section 3.}

\muskip_set:N \(\text{.muskip_set:N = \{\text{muskip}\}}\)

Defines \(\text{.muskip_set:N}\) to set \(\text{.muskip_set:N}\) to \(\text{.muskip_set:N}\) (which must be a muskip expression). If the variable does not exist, it is created globally at the point that the key is set up. The key will require a value at point-of-use unless a default is set.

\prop_put:N \(\text{.prop_put:N = \{\text{property list}\}}\)

Defines \(\text{.prop_put:N}\) to put the \(\text{.prop_put:N}\) onto the \(\text{.prop_put:N}\) stored under the \(\text{.prop_put:N}\). If the variable does not exist, it is created globally at the point that the key is set up.
.skip_set:N \ (key) .skip_set:N = \ (skip)  
Defines \( \langle \text{key} \rangle \) to set \( \langle \text{skip} \rangle \) to \( \langle \text{value} \rangle \) (which must be a skip expression). If the variable does not exist, it is created globally at the point that the key is set up. The key will require a value at point-of-use unless a default is set.

Updated: 2020-01-17

.tl_set:N \ (key) .tl_set:N = \ (token list variable)  
Defines \( \langle \text{key} \rangle \) to set \( \langle \text{token list variable} \rangle \) to \( \langle \text{value} \rangle \). If the variable does not exist, it is created globally at the point that the key is set up.

New: 2015-07-14

.tl_set_x:N \ (key) .tl_set_x:N = \ (token list variable)  
Defines \( \langle \text{key} \rangle \) to set \( \langle \text{token list variable} \rangle \) to \( \langle \text{value} \rangle \), which will be subjected to an \texttt{x}-type expansion (\textit{i.e.} using \texttt{\tl_set:Nx}). If the variable does not exist, it is created globally at the point that the key is set up.

.undefine: \ (key) .undefine:  
Removes the definition of the \( \langle \text{key} \rangle \) within the current scope.

New: 2015-07-14

.value_forbidden:n \ (key) .value_forbidden:n = \texttt{true|false}  
Specifies that \( \langle \text{key} \rangle \) cannot receive a \( \langle \text{value} \rangle \) when used. If a \( \langle \text{value} \rangle \) is given then an error will be issued. Setting the property \texttt{false} cancels the restriction.

New: 2015-07-14

.value_required:n \ (key) .value_required:n = \texttt{true|false}  
Specifies that \( \langle \text{key} \rangle \) must receive a \( \langle \text{value} \rangle \) when used. If a \( \langle \text{value} \rangle \) is not given then an error will be issued. Setting the property \texttt{false} cancels the restriction.

2 Sub-dividing keys

When creating large numbers of keys, it may be desirable to divide them into several sub-groups for a given module. This can be achieved either by adding a sub-division to the module name:

\begin{verbatim}
\keys_define:nn { mymodule / subgroup }
{ key .code:n = code }
\end{verbatim}

or to the key name:

\begin{verbatim}
\keys_define:nn { mymodule }
{ subgroup / key .code:n = code }
\end{verbatim}

As illustrated, the best choice of token for sub-dividing keys in this way is \/. This is because of the method that is used to represent keys internally. Both of the above code fragments set the same key, which has full name \texttt{mymodule/subgroup/key}.

As illustrated in the next section, this subdivision is particularly relevant to making multiple choices.
3 Choice and multiple choice keys

The \texttt{3keys} system supports two types of choice key, in which a series of pre-defined input values are linked to varying implementations. Choice keys are usually created so that the various values are mutually-exclusive: only one can apply at any one time. “Multiple” choice keys are also supported: these allow a selection of values to be chosen at the same time.

Mutually-exclusive choices are created by setting the .\texttt{choice:} property:

\begin{verbatim}
\keys_define:nn { mymodule }
  { key .choice: }
\end{verbatim}

For keys which are set up as choices, the valid choices are generated by creating sub-keys of the choice key. This can be carried out in two ways.

In many cases, choices execute similar code which is dependant only on the name of the choice or the position of the choice in the list of all possibilities. Here, the keys can share the same code, and can be rapidly created using the .\texttt{choices:nn} property.

\begin{verbatim}
\keys_define:nn { mymodule }
{ key .choices:nn =
  { choice-a, choice-b, choice-c }
  
  You\_gave\_choice\_\texttt{-'\tl_use:N \l_keys_choice_tl'}, 
  which\_is\_in\_position\_\texttt{-'\int_use:N \l_keys_choice_int \c_space_tl}
  in\_the\_list.
}
\end{verbatim}

The index \texttt{\l_keys_choice_int} in the list of choices starts at 1.

\begin{verbatim}
\l_keys_choice_int \l_keys_choice_tl
\end{verbatim}

Inside the code block for a choice generated using .\texttt{choices:nn}, the variables \texttt{\l_keys_choice_tl} and \texttt{\l_keys_choice_int} are available to indicate the name of the current choice, and its position in the comma list. The position is indexed from 1. Note that, as with standard key code generated using .\texttt{code:n}, the value passed to the key (i.e. the choice name) is also available as \texttt{#1}.

On the other hand, it is sometimes useful to create choices which use entirely different code from one another. This can be achieved by setting the .\texttt{choice:} property of a key, then manually defining sub-keys.

\begin{verbatim}
\keys_define:nn { mymodule }
{ key .choice:, 
  key / choice-a .code:n = code-a, 
  key / choice-b .code:n = code-b, 
  key / choice-c .code:n = code-c, 
}
\end{verbatim}

It is possible to mix the two methods, but manually-created choices should not use \texttt{\l_keys_choice_tl} or \texttt{\l_keys_choice_int}. These variables do not have defined
behaviour when used outside of code created using \texttt{.choices:nn} (\textit{i.e.} anything might happen).

It is possible to allow choice keys to take values which have not previously been defined by adding code for the special \texttt{unknown} choice. The general behavior of the \texttt{unknown} key is described in Section 5. A typical example in the case of a choice would be to issue a custom error message:

\begin{verbatim}
\keys_define:nn { mymodule }
{
  key .choice:,
  key / choice-a .code:n = code-a,
  key / choice-b .code:n = code-b,
  key / choice-c .code:n = code-c,
  key / unknown .code:n =
    \msg_error:nxxx { mymodule } { unknown-choice }
    { key } % Name of choice key
    { choice-a , choice-b , choice-c } % Valid choices
    { \exp_not:n {#1} } % Invalid choice given
%
%
}
\end{verbatim}

Multiple choices are created in a very similar manner to mutually-exclusive choices, using the properties \texttt{.multichoice:} and \texttt{.multichoices:nn}. As with mutually exclusive choices, multiple choices are define as sub-keys. Thus both

\begin{verbatim}
\keys_define:nn { mymodule }
{
  key .multichoices:nn =
  { choice-a, choice-b, choice-c }
  { You-gave-choice-`\tl_use:N \l_keys_choice_tl',-
    which-is-in-position-
    \int_use:N \l_keys_choice_int \c_space_tl
    in-the-list. }
}
\end{verbatim}

and

\begin{verbatim}
\keys_define:nn { mymodule }
{
  key .multichoice:,
  key / choice-a .code:n = code-a,
  key / choice-b .code:n = code-b,
  key / choice-c .code:n = code-c,
}
\end{verbatim}

are valid.

When a multiple choice key is set
\keys_set:nn { mymodule }
{
  key = { a , b , c } \% 'key' defined as a multiple choice
}

Each choice is applied in turn, equivalent to a clist mapping or to applying each value individually:

\keys_set:nn { mymodule }
{
  key = a ,
  key = b ,
  key = c ,
}

Thus each separate choice will have passed to it the \l_keys_choice_tl and \l_keys_choice_int in exactly the same way as described for .choices:nn.

4 Setting keys

\keys_set:nn \keys_set:(nVnvno)
Updated: 2017-11-14

\keys_set:nn \keys_set:(module) \{(keyval list)\}

 Parses the \{keyval list\}, and sets those keys which are defined for \{module\}. The behaviour on finding an unknown key can be set by defining a special unknown key: this is illustrated later.

For each key processed, information of the full path of the key, the name of the key and the value of the key is available within three token list variables. These may be used within the code of the key.

The value is everything after the =, which may be empty if no value was given. This is stored in \l_keys_value_tl, and is not processed in any way by \keys_set:nn.

The path of the key is a “full” description of the key, and is unique for each key. It consists of the module and full key name, thus for example

\keys_set:nn { mymodule } \{ key-a = some-value \}

has path mymodule/key-a while

\keys_set:nn { mymodule } \{ subset / key-a = some-value \}

has path mymodule/subset/key-a. This information is stored in \l_keys_path_str.

The name of the key is the part of the path after the last /, and thus is not unique. In the preceding examples, both keys have name key-a despite having different paths. This information is stored in \l_keys_key_str.

5 Handling of unknown keys

If a key has not previously been defined (is unknown), \keys_set:nn looks for a special unknown key for the same module, and if this is not defined raises an error indicating that
the key name was unknown. This mechanism can be used for example to issue custom error texts.

\keys_define:nn { mymodule }
{  
  unknown .code:n =  
    You-tried-to-set-key-’\l_keys_key_str’-to-’#1’.  
}

These functions set keys which are known for the ⟨module⟩, and simply ignore other keys. The \keys_set_known:nn function parses the ⟨keyval list⟩, and sets those keys which are defined for ⟨module⟩. Any keys which are unknown are not processed further by the parser. In addition, \keys_set_known:nnN stores the key–value pairs in the ⟨tl⟩ in comma-separated form (i.e. an edited version of the ⟨keyval list⟩). When a ⟨root⟩ is given (\keys_set_known:nnnN), the key–value entries are returned relative to this point in the key tree. When it is absent, only the key name and value are provided. The correct list is returned by nested calls.

6 Selective key setting

In some cases it may be useful to be able to select only some keys for setting, even though these keys have the same path. For example, with a set of keys defined using

\keys_define:nn { mymodule }
{  
  key-one .code:n = { \my_func:n {#1} } ,  
  key-two .tl_set:N = \l_my_a_tl ,  
  key-three .tl_set:N = \l_my_a_tl ,  
  key-four .fp_set:N = \l_my_a_fp ,  
}

the use of \keys_set:nn attempts to set all four keys. However, in some contexts it may only be sensible to set some keys, or to control the order of setting. To do this, keys may be assigned to groups: arbitrary sets which are independent of the key tree. Thus modifying the example to read

\keys_define:nn { mymodule }
{  
  key-one .code:n = { \my_func:n {#1} } ,  
  key-one .groups:n = { first } ,  
  key-two .tl_set:N = \l_my_a_tl ,  
}
assigns \texttt{key-one} and \texttt{key-two} to group \texttt{first}, \texttt{key-three} to group \texttt{second}, while \texttt{key-four} is not assigned to a group.

Selective key setting may be achieved either by selecting one or more groups to be made “active”, or by marking one or more groups to be ignored in key setting.

\begin{verbatim}
\keys_set_filter:nn { \\
\keys_set_filter:nnn { \\
\keys_set_filter:nnnN { \\
\keys_set_filter:nnnnN { \\
\keys_set_groups:nnn { \\
\keys_set_groups:nnnN \\
\keys_if_exist_p:nn *
\keys_if_exist:nnT *
\end{verbatim}

Activates key filtering in an “opt-out” sense: keys assigned to any of the \texttt{\langle groups \rangle} specified are ignored. The \texttt{\langle groups \rangle} are given as a comma-separated list. Unknown keys are not assigned to any group and are thus always set. The key–value pairs for each key which is filtered out are stored in the \texttt{\langle tl \rangle} in a comma-separated form \textit{(i.e. an edited version of the \texttt{\langle keyval list \rangle})}. The \texttt{\keys_set_filter:nn} version skips this stage.

Use of \texttt{\keys_set_filter:nnnN} can be nested, with the correct residual \texttt{\langle keyval list \rangle} returned at each stage. In the version which takes a \texttt{\langle root \rangle} argument, the key list is returned relative to that point in the key tree. In the cases without a \texttt{\langle root \rangle} argument, only the key names and values are returned.

Activates key filtering in an “opt-in” sense: only keys assigned to one or more of the \texttt{\langle groups \rangle} specified are set. The \texttt{\langle groups \rangle} are given as a comma-separated list. Unknown keys are not assigned to any group and are thus never set.

7 Utility functions for keys

\begin{verbatim}
\keys_if_exist_p:nn *
\keys_if_exist:nnT *
\end{verbatim}

Tests if the \texttt{\langle key \rangle} exists for \texttt{\langle module \rangle}, \textit{i.e.} if any code has been defined for \texttt{\langle key \rangle}. 193
Tests if the \langle choice \rangle is defined for the \langle key \rangle within the \langle module \rangle, i.e. if any code has been defined for \langle key \rangle/\langle choice \rangle. The test is false if the \langle key \rangle itself is not defined.

\textbf{8 Low-level interface for parsing key–val lists}

To re-cap from earlier, a key–value list is input of the form

\begin{verbatim}
KeyOne = ValueOne ,
KeyTwo = ValueTwo ,
KeyThree
\end{verbatim}

where each key–value pair is separated by a comma from the rest of the list, and each key–value pair does not necessarily contain an equals sign or a value! Processing this type of input correctly requires a number of careful steps, to correctly account for braces, spaces and the category codes of separators.

While the functions described earlier are used as a high-level interface for processing such input, in special circumstances you may wish to use a lower-level approach. The low-level parsing system converts a \langle key–value list \rangle into \langle keys \rangle and associated \langle values \rangle.

After the parsing phase is completed, the resulting keys and values (or keys alone) are available for further processing. This processing is not carried out by the low-level parser itself, and so the parser requires the names of two functions along with the key–value list. One function is needed to process key–value pairs (it receives two arguments), and a second function is required for keys given without any value (it is called with a single argument).

The parser does not double # tokens or expand any input. Active tokens = and , appearing at the outer level of braces are converted to category “other” (12) so that the parser does not “miss” any due to category code changes. Spaces are removed from the ends of the keys and values. Keys and values which are given in braces have exactly one set removed (after space trimming), thus

\begin{verbatim}
key = {value here},
\end{verbatim}

and

\begin{verbatim}
key = value here,
\end{verbatim}
are treated identically.

\keyval_parse:NNn \{function\}_1 \{function\}_2 \{\textit{key–value list}\}

Parses the \textit{key–value list} into a series of \textit{keys} and associated \textit{values}, or keys alone (if no \textit{value} was given). \textit{function}_1 should take one argument, while \textit{function}_2 should absorb two arguments. After \keyval_parse:NNn has parsed the \textit{key–value list}, \textit{function}_1 is used to process keys given with no value and \textit{function}_2 is used to process keys given with a value. The order of the \textit{keys} in the \textit{key–value list} is preserved. Thus

\keyval_parse:NNn \texttt{\{key1 = value1 , key2 = value2, key3 = , key4 \}}

is converted into an input stream

\texttt{\{key1\} \{value1\}}
\texttt{\{key2\} \{value2\}}
\texttt{\{key3\} \{\}}
\texttt{\{key4\}}

Note that there is a difference between an empty value (an equals sign followed by nothing) and a missing value (no equals sign at all). Spaces are trimmed from the ends of the \textit{key} and \textit{value}, then one outer set of braces is removed from the \textit{key} and \textit{value} as part of the processing.

\texttt{\TeXhackers note: The result is returned within \exp_not:n, which means that the converted input stream does not expand further when appearing in an \texttt{x}-type or \texttt{e}-type argument expansion.}
Part XXII

The \texttt{l3intarray} package: fast global integer arrays

1 \texttt{l3intarray} documentation

For applications requiring heavy use of integers, this module provides arrays which can be accessed in constant time (contrast \texttt{l3seq}, where access time is linear). These arrays have several important features

- The size of the array is fixed and must be given at point of initialisation
- The absolute value of each entry has maximum $2^{30} - 1$ (i.e. one power lower than the usual $\maxint$ ceiling of $2^{31} - 1$)

The use of \texttt{intarray} data is therefore recommended for cases where the need for fast access is of paramount importance.

\begin{verbatim}
\intarray_new:Nn \intarray_new:cn \\
\intarray_new:Nn \intarray_new:cn
\end{verbatim}

Evaluates the integer expression \(\langle\text{size}\rangle\) and allocates an \(\langle\text{integer array variable}\rangle\) with that number of (zero) entries. The variable name should start with \texttt{g_{}} because assignments are always global.

\begin{verbatim}
\intarray_count:N \intarray_count:c \intarray_count:N \intarray_count:c
\end{verbatim}

Expands to the number of entries in the \(\langle\text{integer array variable}\rangle\). Contrarily to \texttt{seq\_count:N} this is performed in constant time.

\begin{verbatim}
\intarray_gset:Nnn \intarray_gset:cnn \\
\intarray_gset:Nnn \intarray_gset:cnn
\end{verbatim}

Stores the result of evaluating the integer expression \(\langle\text{value}\rangle\) into the \(\langle\text{integer array variable}\rangle\) at the (integer expression) \(\langle\text{position}\rangle\). If the \(\langle\text{position}\rangle\) is not between 1 and the \texttt{intarray\_count:N}, or the \(\langle\text{value}\rangle\)'s absolute value is bigger than $2^{30} - 1$, an error occurs. Assignments are always global.

\begin{verbatim}
\intarray_const_from_clist:Nn \intarray_const_from_clist:cn \\
\intarray_const_from_clist:Nn \intarray_const_from_clist:cn
\end{verbatim}

Creates a new constant \(\langle\text{integer array variable}\rangle\) or raises an error if the name is already taken. The \(\langle\text{integer array variable}\rangle\) is set (globally) to contain as its items the results of evaluating each \(\langle\text{integer expression}\rangle\) in the \(\langle\text{comma list}\rangle\).

\begin{verbatim}
\intarray_gzero:N \intarray_gzero:c \intarray_gzero:N \intarray_gzero:c
\end{verbatim}

Sets all entries of the \(\langle\text{integer array variable}\rangle\) to zero. Assignments are always global.
\intarray_item:Nn \intarray_item:cn
\textit{New: 2018-03-29}

\intarray_item:Nn \intarray_item:cn
Expands to the integer entry stored at the (integer expression) \textit{position} in the \textit{integer array variable}. If the (position) is not between 1 and the \intarray_count:N, an error occurs.

\intarray_rand_item:N \intarray_rand_item:c
\textit{New: 2018-05-05}

\intarray_rand_item:N \intarray_rand_item:c
Selects a pseudo-random item of the \textit{integer array}. If the \textit{integer array} is empty, produce an error.

\intarray_show:N \intarray_show:c \intarray_log:N \intarray_log:c
\textit{New: 2018-05-04}

\intarray_show:N \intarray_show:c \intarray_log:N \intarray_log:c
Displays the items in the \textit{integer array variable} in the terminal or writes them in the log file.

1.1 Implementation notes

It is a wrapper around the \fontdimen primitive, used to store arrays of integers (with a restricted range: absolute value at most $2^{30} - 1$). In contrast to \l3seq sequences the access to individual entries is done in constant time rather than linear time, but only integers can be stored. More precisely, the primitive \fontdimen stores dimensions but the \l3intarray package transparently converts these from/to integers. Assignments are always global.

While \LaTeX{}’s memory is extensible, other engines can “only” deal with a bit less than $4 \times 10^6$ entries in all \fontdimen arrays combined (with default TEXLive settings).
Part XXIII
The l3fp package: Floating points

A decimal floating point number is one which is stored as a significand and a separate exponent. The module implements expandably a wide set of arithmetic, trigonometric, and other operations on decimal floating point numbers, to be used within floating point expressions. Floating point expressions support the following operations with their usual precedence.

- Basic arithmetic: addition $x + y$, subtraction $x - y$, multiplication $x \times y$, division $x/y$, square root $\sqrt{x}$, and parentheses.
- Comparison operators: $x < y$, $x \leq y$, $x > y$, $x \geq y$ etc.
- Boolean logic: sign $\text{sign}(x)$, negation $\text{neg}(x)$, conjunction $x \& \& y$, disjunction $x \| y$, ternary operator $x ? y : z$.
- Exponentials: $\exp(x)$, $\ln(x)$, $x^y$, $\logb(x)$.
- Integer factorial: $\text{fact}(x)$.
- Trigonometry: $\sin(x)$, $\cos(x)$, $\tan(x)$, $\cot(x)$, $\sec(x)$, $\csc(x)$ expecting their arguments in radians, and $\sin^d(x)$, $\cos^d(x)$, $\tan^d(x)$, $\cot^d(x)$, $\sec^d(x)$, $\csc^d(x)$ expecting their arguments in degrees.
- Inverse trigonometric functions: $\arcsin(x)$, $\arccos(x)$, $\arctan(x)$, $\arccot(x)$, $\arcsec(x)$, $\arccsc(x)$ giving a result in radians, and $\arcsind(x)$, $\arccosd(x)$, $\arctand(x)$, $\arccotd(x)$, $\arcsecd(x)$, $\arccscd(x)$ giving a result in degrees.
- (not yet) Hyperbolic functions and their inverse functions: $\sinh(x)$, $\cosh(x)$, $\tanh(x)$, $\coth(x)$, $\sech(x)$, $\csch(x)$, and $\text{asinh}(x)$, $\text{acosh}(x)$, $\text{atanh}(x)$, $\text{acoth}(x)$, $\text{asech}(x)$, $\text{acsch}(x)$.
- Extrema: $\max(x_1, x_2, \ldots)$, $\min(x_1, x_2, \ldots)$, $\text{abs}(x)$.
- Rounding functions, controlled by two optional values, $n$ (number of places, 0 by default) and $t$ (behavior on a tie, NaN by default):
  - $\text{trunc}(x, n)$ rounds towards zero,
  - $\text{floor}(x, n)$ rounds towards $-\infty$,
  - $\text{ceil}(x, n)$ rounds towards $+\infty$,
  - $\text{round}(x, n, t)$ rounds to the closest value, with ties rounded to an even value by default, towards zero if $t = 0$, towards $+\infty$ if $t > 0$ and towards $-\infty$ if $t < 0$.

And (not yet) modulo, and “quantize”.
- Random numbers: $\text{rand}()$, $\text{randint}(m, n)$.
- Constants: $\pi$, $\text{deg}$ (one degree in radians).
- Dimensions, automatically expressed in points, e.g., $\text{pc}$ is 12.

198
• Automatic conversion (no need for \texttt{\textbackslash type\_use:N}) of integer, dimension, and skip variables to floating point numbers, expressing dimensions in points and ignoring the stretch and shrink components of skips.

• Tuples: \((x_1, \ldots, x_n)\) that can be stored in variables, added together, multiplied or divided by a floating point number, and nested.

Floating point numbers can be given either explicitly (in a form such as \texttt{1.234e-34}, or \texttt{-0.0001}), or as a stored floating point variable, which is automatically replaced by its current value. A “floating point” is a floating point number or a tuple thereof. See section 9.1 for a description of what a floating point is, section 9.2 for details about how an expression is parsed, and section 9.3 to know what the various operations do. Some operations may raise exceptions (error messages), described in section 7.

An example of use could be the following.

\LaTeX{} can now compute: \(\frac{\sin (3.5)}{2} + 2\cdot 10^{-3}\)

\texttt{\textbackslash \textup{\textbackslash ExploreSyntaxOn} \textbackslash \textup{\textbackslash fp\_to\_decimal:n \{sin(3.5)/2 + 2e-3\} \$.}

The operation \texttt{round} can be used to limit the result’s precision. Adding +0 avoids the possibly undesirable output \texttt{-0}, replacing it by +0. However, the \texttt{fp} module is mostly meant as an underlying tool for higher-level commands. For example, one could provide a function to typeset nicely the result of floating point computations.

\documentclass{article}
\usepackage{xparse, siunitx}
\ExplSyntaxOn
NewDocumentCommand { \calcnum } { m }
{ \num { \fp_to_scientific:n {#1} } }
\ExplSyntaxOff
\begin{document}
\calcnum { 2 \pi * \sin ( 2.3 ^ 5 ) }
\end{document}

See the documentation of \texttt{siunitx} for various options of \texttt{num}.

1 Creating and initialising floating point variables

\texttt{\textbackslash \textup{\textbackslash fp\_new:N} \langle fp\ var\rangle}

Creates a new \texttt{\langle fp\ var\rangle} or raises an error if the name is already taken. The declaration is global. The \texttt{\langle fp\ var\rangle} is initially +0.

\texttt{\textbackslash \textup{\textbackslash fp\_const:Nn} \langle fp\ var\rangle \{ \langle floating point expression\rangle\}}

Creates a new constant \texttt{\langle fp\ var\rangle} or raises an error if the name is already taken. The \texttt{\langle fp\ var\rangle} is set globally equal to the result of evaluating the \texttt{\langle floating point expression\rangle}.

\texttt{\textbackslash \textup{\textbackslash fp\_zero:N} \langle fp\ var\rangle}

Sets the \texttt{\langle fp\ var\rangle} to +0.
2 Setting floating point variables

\fp_set:Nn \langle \text{fp var} \rangle \{ \langle \text{floating point expression} \rangle \}

Sets \langle \text{fp var} \rangle equal to the result of computing the \langle \text{floating point expression} \rangle.

\fp_set_eq:NN \langle \text{fp var}_1 \rangle \langle \text{fp var}_2 \rangle

Sets the floating point variable \langle \text{fp var}_1 \rangle equal to the current value of \langle \text{fp var}_2 \rangle.

\fp_add:Nn \langle \text{fp var} \rangle \{ \langle \text{floating point expression} \rangle \}

Adds the result of computing the \langle \text{floating point expression} \rangle to the \langle \text{fp var} \rangle. This also applies if \langle \text{fp var} \rangle and \langle \text{floating point expression} \rangle evaluate to tuples of the same size.

\fp_sub:Nn \langle \text{fp var} \rangle \{ \langle \text{floating point expression} \rangle \}

Subtracts the result of computing the \langle \text{floating point expression} \rangle from the \langle \text{fp var} \rangle. This also applies if \langle \text{fp var} \rangle and \langle \text{floating point expression} \rangle evaluate to tuples of the same size.

3 Using floating points

\fp_eval:n \{ \langle \text{floating point expression} \rangle \}

Evaluates the \langle \text{floating point expression} \rangle and expresses the result as a decimal number with no exponent. Leading or trailing zeros may be inserted to compensate for the exponent. Non-significant trailing zeros are trimmed, and integers are expressed without a decimal separator. The values ±\infty and NaN trigger an “invalid operation” exception. For a tuple, each item is converted using \fp_eval:n and they are combined as \((\langle \text{fp}_{1}\rangle, \langle \text{fp}_{2}\rangle, \ldots, \langle \text{fp}_{n}\rangle)\) if \(n > 1\) and \(\langle \text{fp}_{1}\rangle\) or () for fewer items. This function is identical to \fp_to_decimal:n.
\fp_sign:n \{\langle \text{fpexpr} \rangle \} \n
Evaluates the \langle \text{fpexpr} \rangle and leaves its sign in the input stream using \fp_eval:n \{\text{sign}(\langle \text{result} \rangle)\}: +1 for positive numbers and for +\infty, -1 for negative numbers and for -\infty, \pm 0 for \pm 0. If the operand is a tuple or is \text{NaN}, then “invalid operation” occurs and the result is 0.

\fp_to_decimal:N \{\langle \text{fp var} \rangle \} \n
Evaluates the \langle \text{fp var} \rangle and expresses the result as a decimal number with no exponent. Leading or trailing zeros may be inserted to compensate for the exponent. Non-significant trailing zeros are trimmed, and integers are expressed without a decimal separator. The values ±\infty and \text{NaN} trigger an “invalid operation” exception. For a tuple, each item is converted using \fp_to_decimal:n and they are combined as \langle (\langle \text{fp} 1 \rangle, \langle \text{fp} 2 \rangle, \ldots \langle \text{fp} n \rangle) \rangle if \text{\textcolor{red}{n > 1}} and \langle (\langle \text{fp} 1 \rangle), \rangle or () for fewer items.

\fp_to_dim:N \{\langle \text{fp var} \rangle \} \n
Evaluates the \langle \text{fp var} \rangle and expresses the result as a dimension (in pt) suitable for use in dimension expressions. The output is identical to \fp_to_decimal:n, with an additional trailing pt (both letter tokens). In particular, the result may be outside the range \([ -2^{14} + 2^{-17}, 2^{14} - 2^{-17} ]\) of valid \TeX{} dimensions, leading to overflow errors if used as a dimension. Tuples, as well as the values ±\infty and \text{NaN}, trigger an “invalid operation” exception.

\fp_to_int:N \{\langle \text{fp var} \rangle \} \n
Evaluates the \langle \text{fp var} \rangle, and rounds the result to the closest integer, rounding exact ties to an even integer. The result may be outside the range \([-2^{31} + 1, 2^{31} - 1]\) of valid \TeX{} integers, leading to overflow errors if used in an integer expression. Tuples, as well as the values ±\infty and \text{NaN}, trigger an “invalid operation” exception.

\fp_to_scientific:N \{\langle \text{fp var} \rangle \} \n
Evaluates the \langle \text{fp var} \rangle and expresses the result in scientific notation: 
\langle \text{optional -}\langle \text{digit}\rangle, \langle 15 \text{ digits}\rangle e{\langle \text{optional sign}\rangle}\langle \text{exponent}\rangle \rangle

The leading \langle \text{digit}\rangle is non-zero except in the case of ±0. The values ±\infty and \text{NaN} trigger an “invalid operation” exception. Normal category codes apply: thus the e is category code 11 (a letter). For a tuple, each item is converted using \fp_to_scientific:n and they are combined as \langle (\langle \text{fp} 1 \rangle, \langle \text{fp} 2 \rangle, \ldots \langle \text{fp} n \rangle) \rangle if \text{\textcolor{red}{n > 1}} and \langle (\langle \text{fp} 1 \rangle), \rangle or () for fewer items.
4 Floating point conditionals

\fp_compare:nNn \{ fpexpr \} \{ relation \} \{ fpexpr2 \} \{ \true \} \{ \false \}

Compares the \{ fpexpr \} and the \{ fpexpr2 \}, and returns \true if the \{ relation \} is obeyed. Two floating points \( x \) and \( y \) may obey four mutually exclusive relations: \( x < y \), \( x = y \), \( x > y \), or \( x ? y \) ("not ordered"). The last case occurs exactly if one or both operands is \NaN or is a tuple, unless they are equal tuples. Note that a \NaN is distinct from any value, even another \NaN, hence \( x = x \) is not true for a \NaN. To test if a value is \NaN, compare it to an arbitrary number with the "not ordered" relation.

\fp_compare:nNnTF \{ <value> \} ? \{ \false \}
\{ \} % <value> is nan
\{ \} % <value> is not nan

Tuples are equal if they have the same number of items and items compare equal (in particular there must be no \NaN). At present any other comparison with tuples yields \{ not ordered \}. This is experimental.

This function is less flexible than \fp_compare:nTF but slightly faster. It is provided for consistency with \int_compare:nNnTF and \dim_compare:nNnTF.
\fp_compare_p:n * \fp_compare:nTF *
\fp_compare:n
{ \fpexpr{1} \relation{1} 
  \ldots 
  \fpexpr{N} \relation{N} 
  \fpexpr{N+1} 
}
\fp_compare:nTF
{ \fpexpr{1} \relation{1} 
  \ldots 
  \fpexpr{N} \relation{N} 
  \fpexpr{N+1} 
}
{ \langle \text{true code} \rangle } { \langle \text{false code} \rangle }

Evaluates the \textit{(floating point expressions)} as described for \texttt{\fp_eval:n} and compares consecutive result using the corresponding \langle \text{relation} \rangle, namely it compares \langle \text{fpexpr} \rangle \langle \text{relation} \rangle \langle \text{fpexpr} \rangle \ldots \langle \text{fpexpr} \rangle \langle \text{relation} \rangle \langle \text{fpexpr} \rangle \langle \text{fpexpr} \rangle +1 \rangle. The test yields \textit{true} if all comparisons are \textit{true}. Each \textit{floating point expression} is evaluated only once.

Contrarily to \texttt{\int_compare:nTF}, all \textit{floating point expressions} are computed, even if one comparison is \textit{false}. Two floating points \(x\) and \(y\) may obey four mutually exclusive relations: \(x < y\), \(x = y\), \(x > y\), or \(x ? y\) ("not ordered"). The last case occurs exactly if one or both operands is \texttt{NaN} or is a tuple, unless they are equal tuples. Each \langle \text{relation} \rangle \text{ can be any } (non-empty) combination of \(\langle, =, \rangle, \text{ and } \texttt{?, plus an optional leading } \texttt{!} \text{ (which negates the } \langle \text{relation} \rangle \text{) may not start with } \texttt{?\rangle}, \text{ as this symbol has a different meaning (in combination with } \texttt{:) within floating point expressions.} \text{ The comparison } x \langle \text{relation} \rangle y \text{ is then } \textit{true} \text{ if the } \langle \text{relation} \rangle \text{ does not start with } \texttt{!} \text{ and the actual relation } (\langle, =, \rangle, \text{ or } \texttt{?}) \text{ between } x \text{ and } y \text{ appears within the } \langle \text{relation} \rangle \text{, or on the contrary if the } \langle \text{relation} \rangle \text{ starts with } \texttt{!} \text{ and the relation between } x \text{ and } y \text{ does not appear within the } \langle \text{relation} \rangle \text{. Common choices of } \langle \text{relation} \rangle \text{ include } \geq \text{ (greater or equal), } \neq \text{ (not equal), } \texttt{!} \text{ or } \leq \rangle \text{ (comparable).}

This function is more flexible than \texttt{\fp_compare:nNnTF} and only slightly slower.

\section{Floating point expression loops}

\texttt{\fp_do_until:nNnn} \quad \texttt{\fp_do_until:nNnn \{ \fpexpr{1} \} \langle \text{relation} \rangle \{ \fpexpr{2} \} \{ \langle \text{code} \rangle \}}

Places the \langle \text{code} \rangle \text{ in the input stream for } \TeX \text{ to process, and then evaluates the relationship between the two } \langle \text{floating point expressions} \rangle \text{ as described for } \texttt{\fp_compare:nNnTF}. \text{ If the test is } \textit{false} \text{ then the } \langle \text{code} \rangle \text{ is inserted into the input stream again and a loop occurs until the } \langle \text{relation} \rangle \text{ is } \textit{true}.

\texttt{\fp_do_while:nNnn} \quad \texttt{\fp_do_while:nNnn \{ \fpexpr{1} \} \langle \text{relation} \rangle \{ \fpexpr{2} \} \{ \langle \text{code} \rangle \}}

Places the \langle \text{code} \rangle \text{ in the input stream for } \TeX \text{ to process, and then evaluates the relationship between the two } \langle \text{floating point expressions} \rangle \text{ as described for } \texttt{\fp_compare:nNnTF}. \text{ If the test is } \textit{true} \text{ then the } \langle \text{code} \rangle \text{ is inserted into the input stream again and a loop occurs until the } \langle \text{relation} \rangle \text{ is } \textit{false}.
\texttt{\textbackslash fp\_until\_do:nNnn} $\star$

\begin{verbatim}
\fp_until_do:nNnn{\texttt{\{\textit{fexpr}_1\} \{\textit{relation}\} \{\texttt{\textit{fexpr}_2}\} \{\texttt{\textit{code}}\}}}
\end{verbatim}

Evaluates the relationship between the two \texttt{floating point expressions} as described for \texttt{\textbackslash fp\_compare:nNnTF}, and then places the \texttt{\textit{code}} in the input stream if the \texttt{\textit{relation}} is \texttt{false}. After the \texttt{\textit{code}} has been processed by \TeX{} the test is repeated, and a loop occurs until the test is \texttt{true}.

\texttt{\textbackslash fp\_while\_do:nNnn} $\star$

\begin{verbatim}
\fp_while_do:nNnn{\texttt{\{\textit{fexpr}_1\} \{\textit{relation}\} \{\texttt{\textit{fexpr}_2}\} \{\texttt{\textit{code}}\}}}
\end{verbatim}

Evaluates the relationship between the two \texttt{floating point expressions} as described for \texttt{\textbackslash fp\_compare:nNnTF}, and then places the \texttt{\textit{code}} in the input stream if the \texttt{\textit{relation}} is \texttt{true}. After the \texttt{\textit{code}} has been processed by \TeX{} the test is repeated, and a loop occurs until the test is \texttt{false}.

\texttt{\textbackslash fp\_do\_until:nn} $\star$

\begin{verbatim}
\fp_do_until:nn{\texttt{\{\textit{fexpr}_1\} \{\textit{relation}\} \{\textit{fexpr}_2\} \{\texttt{\textit{code}}\}}}
\end{verbatim}

Places the \texttt{\textit{code}} in the input stream for \TeX{} to process, and then evaluates the relationship between the two \texttt{floating point expressions} as described for \texttt{\textbackslash fp\_compare:nNnTF}. If the test is \texttt{false} then the \texttt{\textit{code}} is inserted into the input stream again and a loop occurs until the \texttt{\textit{relation}} is \texttt{true}.

\texttt{\textbackslash fp\_do\_while:nn} $\star$

\begin{verbatim}
\fp_do_while:nn{\texttt{\{\textit{fexpr}_1\} \{\textit{relation}\} \{\textit{fexpr}_2\} \{\texttt{\textit{code}}\}}}
\end{verbatim}

Places the \texttt{\textit{code}} in the input stream for \TeX{} to process, and then evaluates the relationship between the two \texttt{floating point expressions} as described for \texttt{\textbackslash fp\_compare:nNnTF}. If the test is \texttt{true} then the \texttt{\textit{code}} is inserted into the input stream again and a loop occurs until the \texttt{\textit{relation}} is \texttt{false}.

\texttt{\textbackslash fp\_until\_do:nn} $\star$

\begin{verbatim}
\fp_until_do:nn{\texttt{\{\textit{fexpr}_1\} \{\textit{relation}\} \{\texttt{\textit{fexpr}_2}\} \{\texttt{\textit{code}}\}}}
\end{verbatim}

Evaluates the relationship between the two \texttt{floating point expressions} as described for \texttt{\textbackslash fp\_compare:nNnTF}, and then places the \texttt{\textit{code}} in the input stream if the \texttt{\textit{relation}} is \texttt{false}. After the \texttt{\textit{code}} has been processed by \TeX{} the test is repeated, and a loop occurs until the test is \texttt{true}.

\texttt{\textbackslash fp\_while\_do:nn} $\star$

\begin{verbatim}
\fp_while_do:nn{\texttt{\{\textit{fexpr}_1\} \{\textit{relation}\} \{\texttt{\textit{fexpr}_2}\} \{\texttt{\textit{code}}\}}}
\end{verbatim}

Evaluates the relationship between the two \texttt{floating point expressions} as described for \texttt{\textbackslash fp\_compare:nNnTF}, and then places the \texttt{\textit{code}} in the input stream if the \texttt{\textit{relation}} is \texttt{true}. After the \texttt{\textit{code}} has been processed by \TeX{} the test is repeated, and a loop occurs until the test is \texttt{false}.

204
This function first evaluates the \langle initial value \rangle, \langle step \rangle and \langle final value \rangle, each of which should be a floating point expression evaluating to a floating point number, not a tuple. The \langle function \rangle is then placed in front of each \langle value \rangle from the \langle initial value \rangle to the \langle final value \rangle in turn (using \langle step \rangle between each \langle value \rangle). The \langle step \rangle must be non-zero. If the \langle step \rangle is positive, the loop stops when the \langle value \rangle becomes larger than the \langle final value \rangle. If the \langle step \rangle is negative, the loop stops when the \langle value \rangle becomes smaller than the \langle final value \rangle. The \langle function \rangle should absorb one numerical argument. For example:

\cs_set:Npn \my_func:n #1 { \[I saw #1\] \quad }
\fp_step_function:nnnN { 1.0 } { 0.1 } { 1.5 } \my_func:n

would print

[I saw 1.0] [I saw 1.1] [I saw 1.2] [I saw 1.3] [I saw 1.4] [I saw 1.5]

\textbf{\TeX} hackers note: Due to rounding, it may happen that adding the \langle step \rangle to the \langle value \rangle does not change the \langle value \rangle; such cases give an error, as they would otherwise lead to an infinite loop.

This function first evaluates the \langle initial value \rangle, \langle step \rangle and \langle final value \rangle, all of which should be floating point expressions evaluating to a floating point number, not a tuple. Then for each \langle value \rangle from the \langle initial value \rangle to the \langle final value \rangle in turn (using \langle step \rangle between each \langle value \rangle), the \langle code \rangle is inserted into the input stream with \#1 replaced by the current \langle value \rangle. Thus the \langle code \rangle should define a function of one argument (\#1).

This function first evaluates the \langle initial value \rangle, \langle step \rangle and \langle final value \rangle, all of which should be floating point expressions evaluating to a floating point number, not a tuple. Then for each \langle value \rangle from the \langle initial value \rangle to the \langle final value \rangle in turn (using \langle step \rangle between each \langle value \rangle), the \langle code \rangle is inserted into the input stream, with the \langle tl var \rangle defined as the current \langle value \rangle. Thus the \langle code \rangle should make use of the \langle tl var \rangle.

6 Some useful constants, and scratch variables

\c_zero_fp
\c_minus_zero_fp

Zero, with either sign.

\c_one_fp

One as an fp: useful for comparisons in some places.
Infinity, with either sign. These can be input directly in a floating point expression as `inf` and `-inf`.

The value of the base of the natural logarithm, `e = exp(1)`.

The value of π. This can be input directly in a floating point expression as `pi`.

The value of 1° in radians. Multiply an angle given in degrees by this value to obtain a result in radians. Note that trigonometric functions expecting an argument in radians or in degrees are both available. Within floating point expressions, this can be accessed as `deg`.

Scratch floating points for local assignment. These are never used by the kernel code, and so are safe for use with any LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

Scratch floating points for global assignment. These are never used by the kernel code, and so are safe for use with any LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

7 Floating point exceptions

The functions defined in this section are experimental, and their functionality may be altered or removed altogether.

“Exceptions” may occur when performing some floating point operations, such as `0 / 0`, or `10 ** 1e9999`. The relevant IEEE standard defines 5 types of exceptions, of which we implement 4.

- **Overflow** occurs whenever the result of an operation is too large to be represented as a normal floating point number. This results in `±∞`.

- **Underflow** occurs whenever the result of an operation is too close to 0 to be represented as a normal floating point number. This results in ±0.

- **Invalid operation** occurs for operations with no defined outcome, for instance `0/0` or `sin(∞)`, and results in a NaN. It also occurs for conversion functions whose target type does not have the appropriate infinite or NaN value (e.g., `\fp_to_dim:n`).

- **Division by zero** occurs when dividing a non-zero number by 0, or when evaluating functions at poles, e.g., `ln(0)` or `cot(0)`. This results in `±∞`. 
Inexact occurs whenever the result of a computation is not exact, in other words, almost always. At the moment, this exception is entirely ignored in \LaTeX.

To each exception we associate a “flag”: \texttt{fp\_overflow}, \texttt{fp\_underflow}, \texttt{fp\_invalid\_operation} and \texttt{fp\_division\_by\_zero}. The state of these flags can be tested and modified with commands from \texttt{l3flag}.

By default, the “invalid operation” exception triggers an (expandable) error, and raises the corresponding flag. Other exceptions raise the corresponding flag but do not trigger an error. The behaviour when an exception occurs can be modified (using \texttt{\fp\_trap:nn}) to either produce an error and raise the flag, or only raise the flag, or do nothing at all.

\begin{verbatim}
\fp\_trap:nn {⟨exception⟩} {⟨trap type⟩}
\end{verbatim}

All occurrences of the ⟨exception⟩ (overflow, underflow, invalid\_operation or division\_by\_zero) within the current group are treated as ⟨trap type⟩, which can be

- none: the ⟨exception⟩ will be entirely ignored, and leave no trace;
- flag: the ⟨exception⟩ will turn the corresponding flag on when it occurs;
- error: additionally, the ⟨exception⟩ will halt the \TeX\ run and display some information about the current operation in the terminal.

This function is experimental, and may be altered or removed.

Flags denoting the occurrence of various floating-point exceptions.

\begin{verbatim}
\texttt{\fp\_show:N {⟨fp var⟩}} \texttt{\fp\_show:N {⟨floating point expression⟩}}
\end{verbatim}

Evaluates the ⟨floating point expression⟩ and displays the result in the terminal.

\begin{verbatim}
\texttt{\fp\_log:N {⟨fp var⟩}} \texttt{\fp\_log:N {⟨floating point expression⟩}}
\end{verbatim}

Evaluates the ⟨floating point expression⟩ and writes the result in the log file.

8 Viewing floating points
9 Floating point expressions

9.1 Input of floating point numbers

We support four types of floating point numbers:

- \(\pm m \cdot 10^n\), a floating point number, with integer \(1 \leq m \leq 10^{16}\), and \(-10000 \leq n \leq 10000\);
- \(\pm 0\), zero, with a given sign;
- \(\pm \infty\), infinity, with a given sign;
- \(\text{NaN}\), is “not a number”, and can be either quiet or signalling (not yet: this distinction is currently unsupported);

Normal floating point numbers are stored in base 10, with up to 16 significant figures. On input, a normal floating point number consists of:

- \(\langle \text{sign} \rangle\): a possibly empty string of + and – characters;
- \(\langle \text{significand} \rangle\): a non-empty string of digits together with zero or one dot;
- \(\langle \text{exponent} \rangle\) optionally: the character \(e\) or \(E\), followed by a possibly empty string of + and – tokens, and a non-empty string of digits.

The sign of the resulting number is + if \(\langle \text{sign} \rangle\) contains an even number of –, and – otherwise, hence, an empty \(\langle \text{sign} \rangle\) denotes a non-negative input. The stored significand is obtained from \(\langle \text{significand} \rangle\) by omitting the decimal separator and leading zeros, and rounding to 16 significant digits, filling with trailing zeros if necessary. In particular, the value stored is exact if the input \(\langle \text{significand} \rangle\) has at most 16 digits. The stored \(\langle \text{exponent} \rangle\) is obtained by combining the input \(\langle \text{exponent} \rangle\) (0 if absent) with a shift depending on the position of the significand and the number of leading zeros.

A special case arises if the resulting \(\langle \text{exponent} \rangle\) is either too large or too small for the floating point number to be represented. This results either in an overflow (the number is then replaced by \(\pm \infty\)), or an underflow (resulting in \(\pm 0\)).

The result is thus \(\pm 0\) if and only if \(\langle \text{significand} \rangle\) contains no non-zero digit (i.e., consists only in characters 0, and an optional period), or if there is an underflow. Note that a single dot is currently a valid floating point number, equal to \(+0\), but that is not guaranteed to remain true.

The \(\langle \text{significand} \rangle\) must be non-empty, so \(e1\) and \(e-1\) are not valid floating point numbers. Note that the latter could be mistaken with the difference of “e” and 1. To avoid confusions, the base of natural logarithms cannot be input as \(e\) and should be input as \(\exp(1)\) or \(\text{\$c\_e\_fp}\) (which is faster).

Special numbers are input as follows:

- \(\text{inf}\) represents \(+\infty\), and can be preceded by any \(\langle \text{sign} \rangle\), yielding \(\pm \infty\) as appropriate.
- \(\text{nan}\) represents a (quiet) non-number. It can be preceded by any sign, but that sign is ignored.
- Any unrecognizable string triggers an error, and produces a \(\text{NaN}\).
- Note that commands such as \(\text{\$inf}\), \(\text{\$pi}\), or \(\text{\$sin}\) do not work in floating point expressions. They may silently be interpreted as completely unexpected numbers, because integer constants (allowed in expressions) are commonly stored as mathematical characters.
9.2 Precedence of operators

We list here all the operations supported in floating point expressions, in order of decreasing precedence: operations listed earlier bind more tightly than operations listed below them.

- Function calls ($\sin$, $\ln$, etc).
- Binary $\star\star$ and $\sim$ (right associative).
- Unary $+$, $-$, $!$.
- Implicit multiplication by juxtaposition ($\pi$) when neither factor is in parentheses.
- Binary $\times$ and $/$, implicit multiplication by juxtaposition with parentheses (for instance $3(4+5)$).
- Binary $+$ and $-$.
- Comparisons $\geq$, $\neq$, $<$, $>$, etc.
- Logical and, denoted by $\&\&$.
- Logical or, denoted by $||$.
- Ternary operator $?:$ (right associative).
- Comma (to build tuples).

The precedence of operations can be overridden using parentheses. In particular, the precedence of juxtaposition implies that

\[
\frac{1}{2\pi} = \frac{1}{(2\pi)},
\]
\[
\frac{1}{2\pi}(\pi + \pi) = (2\pi)^{-1}(\pi + \pi) \approx 1,
\]
\[
\sin 2\pi = \sin(2\pi) \pi \neq 0,
\]
\[
2^\star\star \max(3,5) = 2^\star\star \max(3,5) = 20,
\]
\[
1\text{in}/1\text{cm} = (1\text{in})/(1\text{cm}) = 2.54.
\]

Functions are called on the value of their argument, contrarily to \TeX macros.

9.3 Operations

We now present the various operations allowed in floating point expressions, from the lowest precedence to the highest. When used as a truth value, a floating point expression is false if it is $\pm 0$, and true otherwise, including when it is \texttt{NaN} or a tuple such as (0, 0). Tuples are only supported to some extent by operations that work with truth values ($?:$, $1\text{I}$, $\&\&$, $!$), by comparisons ($\!\neq\!\neq$?), and by $\star$, $\pm$, $\div$. Unless otherwise specified, providing a tuple as an argument of any other operation yields the “invalid operation” exception and a \texttt{NaN} result.
The ternary operator ?:: results in \langle\text{operand}_2\rangle if \langle\text{operand}_1\rangle is true (not ±0), and \langle\text{operand}_3\rangle if \langle\text{operand}_1\rangle is false (±0). All three \langle\text{operands}\rangle are evaluated in all cases; they may be tuples. The operator is right associative, hence

\begin{verbatim}
\fp_eval:n { \langle\text{operand}_1\rangle ? \langle\text{operand}_2\rangle : \langle\text{operand}_3\rangle }
\end{verbatim}

first tests whether \(1 + 3 > 4\); since this isn’t true, the branch following : is taken, and \(2 + 4 > 5\) is compared; since this is true, the branch before : is taken, and everything else is (evaluated then) ignored. That allows testing for various cases in a concise manner, with the drawback that all computations are made in all cases.

\begin{verbatim}
\fp_eval:n { \langle\text{operand}_1\rangle || \langle\text{operand}_2\rangle }
\end{verbatim}

If \langle\text{operand}_1\rangle is true (not ±0), use that value, otherwise the value of \langle\text{operand}_2\rangle. Both \langle\text{operands}\rangle are evaluated in all cases; they may be tuples. In \langle\text{operand}_1\rangle \| \langle\text{operand}_2\rangle || \ldots || \langle\text{operands}_n\rangle, the first true (nonzero) \langle\text{operand}\rangle is used and if all are zero the last one (±0) is used.

\begin{verbatim}
\fp_eval:n { \langle\text{operand}_1\rangle \&\& \langle\text{operand}_2\rangle }
\end{verbatim}

If \langle\text{operand}_1\rangle is false (equal to ±0), use that value, otherwise the value of \langle\text{operand}_2\rangle. Both \langle\text{operands}\rangle are evaluated in all cases; they may be tuples. In \langle\text{operand}_1\rangle && \langle\text{operand}_2\rangle && \ldots && \langle\text{operands}_n\rangle, the first false (±0) \langle\text{operand}\rangle is used and if none is zero the last one is used.

\begin{verbatim}
\fp_eval:n { \langle\text{operand}_1\rangle \langle\text{relation}_1\rangle \langle\text{operand}_1+1\rangle
\end{verbatim}

Each \langle\text{relation}\rangle consists of a non-empty string of <, =, >, and ?, optionally preceded by !, and may not start with ?. This evaluates to +1 if all comparisons \langle\text{operand}_1\rangle \langle\text{relation}_1\rangle \langle\text{operand}_1+1\rangle are true, and +0 otherwise. All \langle\text{operands}\rangle are evaluated (once) in all cases. See \fp_compare:nTF for details.

\begin{verbatim}
\fp_eval:n { \langle\text{operand}_1\rangle + \langle\text{operand}_2\rangle }
\fp_eval:n { \langle\text{operand}_1\rangle - \langle\text{operand}_2\rangle }
\end{verbatim}

Computes the sum or the difference of its two \langle\text{operands}\rangle. The “invalid operation” exception occurs for \(\infty - \infty\). “Underflow” and “overflow” occur when appropriate. These operations supports the itemwise addition or subtraction of two tuples, but if they have a different number of items the “invalid operation” exception occurs and the result is NaN.
Computes the product or the ratio of its two operands. The “invalid operation” exception occurs for $\infty/\infty$, $0/0$, or $0 \cdot \infty$. “Division by zero” occurs when dividing a finite non-zero number by ±0. “Underflow” and “overflow” occur when appropriate. When $\langle operand_1 \rangle$ is a tuple and $\langle operand_2 \rangle$ is a floating point number, each item of $\langle operand_1 \rangle$ is multiplied or divided by $\langle operand_2 \rangle$. Multiplication also supports the case where $\langle operand_1 \rangle$ is a floating point number and $\langle operand_2 \rangle$ a tuple. Other combinations yield an “invalid operation” exception and a NaN result.

The unary + does nothing, the unary - changes the sign of the $\langle operand \rangle$ (for a tuple, of all its components), and ! $\langle operand \rangle$ evaluates to 1 if $\langle operand \rangle$ is false (is ±0) and 0 otherwise (this is the not boolean function). Those operations never raise exceptions.

Raises $\langle operand_1 \rangle$ to the power $\langle operand_2 \rangle$. This operation is right associative, hence $2 ** 2 ** 3 = 256$. If $\langle operand_1 \rangle$ is negative or −0 then: the result’s sign is + if the $\langle operand_2 \rangle$ is infinite and $(−1)^q$ if the $\langle operand_2 \rangle$ is $p/5^q$ with $p, q$ integers; the result is +0 if abs($\langle operand_1 \rangle$)** $\langle operand_2 \rangle$ evaluates to zero; in other cases the “invalid operation” exception occurs because the sign cannot be determined. “Division by zero” occurs when raising ±0 to a finite strictly negative power. “Underflow” and “overflow” occur when appropriate. If either operand is a tuple, “invalid operation” occurs.

Computes the absolute value of the $\langle fpexpr \rangle$. If the operand is a tuple, “invalid operation” occurs. This operation does not raise exceptions in other cases. See also $\backslash fp\_abs:n$.

Computes the exponential of the $\langle fpexpr \rangle$. “Underflow” and “overflow” occur when appropriate. If the operand is a tuple, “invalid operation” occurs.

Computes the factorial of the $\langle fpexpr \rangle$. If the $\langle fpexpr \rangle$ is an integer between −0 and 3248 included, the result is finite and correctly rounded. Larger positive integers give $+\infty$ with “overflow”, while $\backslash fact (+\infty) = +\infty$ and $\backslash fact (\text{nan}) = \text{nan}$ with no exception. All other inputs give NaN with the “invalid operation” exception.

Computes the natural logarithm of the $\langle fpexpr \rangle$. Negative numbers have no (real) logarithm, hence the “invalid operation” is raised in that case, including for ln(+0) = $−\infty$. “Division by zero” occurs when evaluating ln(+0) = $−\infty$. “Underflow” and “overflow” occur when appropriate. If the operand is a tuple, “invalid operation” occurs.
Determines the exponent of the \( \langle \text{fpexpr} \rangle \), namely the floor of the base-10 logarithm of its absolute value. “Division by zero” occurs when evaluating \( \log_{10}(\pm 0) = -\infty \). Other special values are \( \log_{10}(\pm \infty) = +\infty \) and \( \log_{10}(\text{NaN}) = \text{NaN} \). If the operand is a tuple or is NaN, then “invalid operation” occurs and the result is NaN.

```
\fp_eval:n { logb( \langle \text{fpexpr} \rangle ) }  
```

New: 2018-11-03

Evaluates each \( \langle \text{fpexpr} \rangle \) and computes the largest (smallest) of those. If any of the \( \langle \text{fpexpr} \rangle \) is a NaN or tuple, the result is NaN. If any operand is a tuple, “invalid operation” occurs; these operations do not raise exceptions in other cases.

```
\fp_eval:n { max( \langle \text{fpexpr} \rangle_1 , \langle \text{fpexpr} \rangle_2 , \ldots ) }  
\fp_eval:n { min( \langle \text{fpexpr} \rangle_1 , \langle \text{fpexpr} \rangle_2 , \ldots ) }  
```

Updated: 2015-08-08

Only round accepts a third argument. Evaluates \( \langle \text{fpexpr}_1 \rangle = x \) and \( \langle \text{fpexpr}_2 \rangle = n \) and \( \langle \text{fpexpr}_3 \rangle = t \) then rounds \( x \) to \( n \) places. If \( n \) is an integer, this rounds \( x \) to a multiple of \( 10^{-n} \); if \( n = +\infty \), this always yields \( x \); if \( n = -\infty \), this yields one of \( \pm 0 \), \( \pm \infty \), or NaN; if \( n = \text{NaN} \), this yields NaN; if \( n \) is neither \( \pm \infty \) nor an integer, then an “invalid operation” exception is raised. When \( \langle \text{fpexpr}_2 \rangle \) is omitted, \( n = 0 \), i.e., \( \langle \text{fpexpr}_1 \rangle \) is rounded to an integer. The rounding direction depends on the function.

- **round** yields the multiple of \( 10^{-n} \) closest to \( x \), with ties (\( x \) half-way between two such multiples) rounded as follows. If \( t \) is \text{nan} (or not given) the even multiple is chosen (“ties to even”), if \( t = \pm 0 \) the multiple closest to 0 is chosen (“ties to zero”), if \( t \) is positive/negative the multiple closest to \( \infty/-\infty \) is chosen (“ties towards positive/negative infinity”).
- **floor** yields the largest multiple of \( 10^{-n} \) smaller or equal to \( x \) (“round towards negative infinity”);
- **ceil** yields the smallest multiple of \( 10^{-n} \) greater or equal to \( x \) (“round towards positive infinity”);
- **trunc** yields a multiple of \( 10^{-n} \) with the same sign as \( x \) and with the largest absolute value less than that of \( x \) (“round towards zero”).

“Overflow” occurs if \( x \) is finite and the result is infinite (this can only happen if \( \langle \text{fpexpr}_2 \rangle < -9984 \)). If any operand is a tuple, “invalid operation” occurs.

```
\fp_eval:n { round( \langle \text{fpexpr} \rangle ) }  
\fp_eval:n { round( \langle \text{fpexpr}_1 \rangle , \langle \text{fpexpr}_2 \rangle ) }  
\fp_eval:n { round( \langle \text{fpexpr}_1 \rangle , \langle \text{fpexpr}_2 \rangle , \langle \text{fpexpr}_3 \rangle ) }  
```

```
\fp_eval:n { sign( \langle \text{fpexpr} \rangle ) }  
```

Evaluates the \( \langle \text{fpexpr} \rangle \) and determines its sign: \( +1 \) for positive numbers and for \( +\infty, -1 \) for negative numbers and for \( -\infty, \pm 0 \) for \( \pm 0 \), and NaN for NaN. If the operand is a tuple, “invalid operation” occurs. This operation does not raise exceptions in other cases.

212
Computes the sine, cosine, tangent, cotangent, cosecant, or secant of the \( \langle \text{fpexpr} \rangle \) given in radians. For arguments given in degrees, see \text{sind}, \text{cosd}, etc. Note that since \( \pi \) is irrational, \( \sin(8\pi) \) is not quite zero, while its analogue \( \text{sind}(8 \times 180) \) is exactly zero. The trigonometric functions are undefined for an argument of \( \pm \infty \), leading to the “invalid operation” exception. Additionally, evaluating tangent, cotangent, cosecant, or secant at one of their poles leads to a “division by zero” exception. “Underflow” and “overflow” occur when appropriate. If the operand is a tuple, “invalid operation” occurs.

\[
\begin{align*}
\sin & \quad \text{\texttt{fp_eval:n \{ \sin( \langle \text{fpexpr} \rangle ) \}}} \\
\cos & \quad \text{\texttt{fp_eval:n \{ \cos( \langle \text{fpexpr} \rangle ) \}}} \\
\tan & \quad \text{\texttt{fp_eval:n \{ \tan( \langle \text{fpexpr} \rangle ) \}}} \\
\cot & \quad \text{\texttt{fp_eval:n \{ \cot( \langle \text{fpexpr} \rangle ) \}}} \\
\csc & \quad \text{\texttt{fp_eval:n \{ \csc( \langle \text{fpexpr} \rangle ) \}}} \\
\sec & \quad \text{\texttt{fp_eval:n \{ \sec( \langle \text{fpexpr} \rangle ) \}}} \\
\end{align*}
\]

Updated: 2013-11-17

\end{align*}
\]

New: 2013-11-02

213
Those functions yield an angle in radians: \text{atan} and \text{acot}d are their analogs in degrees. The one-argument versions compute the arctangent or arccotangent of the \text{\langle fexpr \rangle}: arctangent takes values in the range \([-\pi/2, \pi/2]\), and arccotangent in the range \([0, \pi]\). The two-argument arctangent computes the angle in polar coordinates of the point with Cartesian coordinates \((\text{\langle fexpr\rangle}_2, \text{\langle fexpr\rangle}_1)\): this is the arctangent of \(\text{\langle fexpr\rangle}_1/\text{\langle fexpr\rangle}_2\), possibly shifted by \(\pi\) depending on the signs of \(\text{\langle fexpr\rangle}_1\) and \(\text{\langle fexpr\rangle}_2\). The two-argument arccotangent computes the angle in polar coordinates of the point \((\text{\langle fexpr\rangle}_1, \text{\langle fexpr\rangle}_2)\), equal to the arctangent of \(\text{\langle fexpr\rangle}_1/\text{\langle fexpr\rangle}_2\), possibly shifted by \(\pi\). Both two-argument functions take values in the wider range \([-\pi, \pi]\). The ratio \(\text{\langle fexpr\rangle}_1/\text{\langle fexpr\rangle}_2\) need not be defined for the two-argument arctangent: when both expressions yield \(\pm 0\), or when both yield \(\pm \infty\), the resulting angle is one of \(\{\pm \pi/4, \pm 3\pi/4\}\) depending on signs. The “underflow” exception can occur. If any operand is a tuple, “invalid operation” occurs.

Those functions yield an angle in degrees: \text{atan} and \text{acot}d are their analogs in radians. The one-argument versions compute the arctangent or arccotangent of the \text{\langle fexpr \rangle}: arctangent takes values in the range \([-90, 90]\), and arccotangent in the range \([0, 180]\). The two-argument arctangent computes the angle in polar coordinates of the point with Cartesian coordinates \((\text{\langle fexpr\rangle}_2, \text{\langle fexpr\rangle}_1)\): this is the arctangent of \(\text{\langle fexpr\rangle}_1/\text{\langle fexpr\rangle}_2\), possibly shifted by 180 depending on the signs of \(\text{\langle fexpr\rangle}_1\) and \(\text{\langle fexpr\rangle}_2\). The two-argument arccotangent computes the angle in polar coordinates of the point \((\text{\langle fexpr\rangle}_1, \text{\langle fexpr\rangle}_2)\), equal to the arctangent of \(\text{\langle fexpr\rangle}_1/\text{\langle fexpr\rangle}_2\), possibly shifted by 180. Both two-argument functions take values in the wider range \([-180, 180]\]. The ratio \(\text{\langle fexpr\rangle}_1/\text{\langle fexpr\rangle}_2\) need not be defined for the two-argument arctangent: when both expressions yield \(\pm 0\), or when both yield \(\pm \infty\), the resulting angle is one of \(\{\pm 45, \pm 135\}\) depending on signs. The “underflow” exception can occur. If any operand is a tuple, “invalid operation” occurs.

Computes the square root of the \text{\langle fexpr \rangle}. The “invalid operation” is raised when the \text{\langle fexpr \rangle} is negative or is a tuple; no other exception can occur. Special values yield \(\sqrt{-0} = -0\), \(\sqrt{+0} = +0\), \(\sqrt{-\infty} = +\infty\) and \(\sqrt{\text{NaN}} = \text{NaN}\).
\fp_eval:n \{ rand() \}

New: 2016-12-05

Produces a pseudo-random floating-point number (multiple of $10^{-16}$) between 0 included and 1 excluded. This is not available in older versions of \LaTeX. The random seed can be queried using \sys_rand_seed: and set using \sys_gset_rand_seed:n.

\TeX hackers note: This is based on pseudo-random numbers provided by the engine’s primitive \pdfuniformdeviate in pdf\TeX, \up\TeX, up\TeX and \uniformdeviate in Lua\TeX and \Xe\TeX. The underlying code is based on Metapost, which follows an additive scheme recommended in Section 3.6 of “The Art of Computer Programming, Volume 2”.

While we are more careful than \uniformdeviate to preserve uniformity of the underlying stream of 28-bit pseudo-random integers, these pseudo-random numbers should of course not be relied upon for serious numerical computations nor cryptography.

\fp_eval:n \{ randint( \{fpxpr\} ) \}
\fp_eval:n \{ randint( \{fpxpr\}_1, \{fpxpr\}_2 ) \}

New: 2016-12-05

Produces a pseudo-random integer between 1 and \{fpxpr\} or between \{fpxpr\}_1 and \{fpxpr\}_2 inclusive. The bounds must be integers in the range \((-10^{16}, 10^{16})\) and the first must be smaller or equal to the second. See rand for important comments on how these pseudo-random numbers are generated.

inf

The special values \(+\infty, -\infty\), and NaN are represented as inf, -inf and nan (see \c_-inf_fp, \c_minus_inf_fp and \c_nan_fp).

pi

The value of \(\pi\) (see \c_pi_fp).

deg

The value of \(1^\circ\) in radians (see \c_one_degree_fp).

215
Those units of measurement are equal to their values in pt, namely

\[\begin{align*}
1\text{ in} &= 72.27\text{pt} \\
1\text{pt} &= 1\text{pt} \\
1\text{pc} &= 12\text{pt} \\
1\text{cm} &= \frac{1}{2.54}\text{ in} = 28.45275590551181\text{pt} \\
1\text{mm} &= \frac{1}{25.4}\text{ in} = 2.845275590551181\text{pt} \\
1\text{dd} &= 0.376065\text{mm} = 1.07000856496063\text{pt} \\
1\text{cc} &= 12\text{dd} = 12.8401027952756\text{pt} \\
1\text{nd} &= 0.375\text{mm} = 1.066978346456693\text{pt} \\
1\text{nc} &= 12\text{nd} = 12.80374015748031\text{pt} \\
1\text{bp} &= \frac{1}{72}\text{ in} = 1.00375\text{pt} \\
1\text{sp} &= 2^{-16}\text{pt} = 1.52587890625\text{e} - 5\text{pt}.
\end{align*}\]

The values of the (font-dependent) units \texttt{em} and \texttt{ex} are gathered from \TeX{} when the surrounding floating point expression is evaluated.

Other names for 1 and +0.

\texttt{\fp_abs:n}\hspace{1em} \texttt{\fp_abs:n \langle floating point expression\rangle}

\texttt{\fp_abs:n}\hspace{1em} Evaluates the \langle floating point expression\rangle as described for \texttt{\fp_eval:n} and leaves the absolute value of the result in the input stream. If the argument is ±\infty, NaN or a tuple, “invalid operation” occurs. Within floating point expressions, \texttt{abs()} can be used; it accepts ±\infty and NaN as arguments.

\texttt{\fp_max:nn} \hspace{1em} \texttt{\fp_min:nn}

\texttt{\fp_max:nn \langle fp expression 1\rangle \langle fp expression 2\rangle}\hspace{1em} \texttt{\fp_min:nn \langle fp expression 1\rangle \langle fp expression 2\rangle}

\texttt{\fp_max:nn}\hspace{1em} \texttt{\fp_min:nn}\hspace{1em} Evaluates the \langle floating point expressions\rangle as described for \texttt{\fp_eval:n} and leaves the resulting larger (max) or smaller (min) value in the input stream. If the argument is a tuple, “invalid operation” occurs, but no other case raises exceptions. Within floating point expressions, \texttt{max()} and \texttt{min()} can be used.

10 Disclaimer and roadmap

The package may break down if the escape character is among 0123456789+, or if it receives a \TeX{} primitive conditional affected by \texttt{\exp_not:N}.

The following need to be done. I’ll try to time-order the items.

- Function to count items in a tuple (and to determine if something is a tuple).
- Decide what exponent range to consider.

216
• Support signalling \texttt{nan}.
• Modulo and remainder, and rounding function \texttt{quantize} (and its friends analogous to \texttt{trunc}, \texttt{ceil}, \texttt{floor}).
• \texttt{\textbackslash fp\_format:nn \{fpxpr\} \{format\}}, but what should \texttt{\{format\}} be? More general pretty printing?
• Add \texttt{and}, \texttt{or}, \texttt{xor}? Perhaps under the names \texttt{all}, \texttt{any}, and \texttt{xor}?
• Add $\log(x,b)$ for logarithm of $x$ in base $b$.
• \texttt{hypot} (Euclidean length). Cartesian-to-polar transform.
• Hyperbolic functions \texttt{cosh}, \texttt{sinh}, \texttt{tanh}.
• Inverse hyperbolics.
• Base conversion, input such as \texttt{0xAB.CDEF}.
• Factorial (not with \texttt{!}), gamma function.
• Improve coefficients of the \texttt{sin} and \texttt{tan} series.
• Treat upper and lower case letters identically in identifiers, and ignore underscores.
• Add an \texttt{array(1,2,3)} and \texttt{i=\text{complex}(0,1)}.
• Provide an experimental \texttt{map} function? Perhaps easier to implement if it is a single character, \texttt{@sin(1,2)}?
• Provide an \texttt{isnan} function analogue of \texttt{\textbackslash fp\_if\_nan:nTF}?
• Support keyword arguments?

\texttt{Pgfmath} also provides box-measurements (depth, height, width), but boxes are not possible expandably.

Bugs, and tests to add.

• Check that functions are monotonic when they should.
• Add exceptions to \texttt{?:}, \texttt{!\texttt{<=>}}, \texttt{&&}, \texttt{||}, and \texttt{!}.
• Logarithms of numbers very close to 1 are inaccurate.
• When rounding towards $-\infty$, \texttt{\textbackslash dim\_to\_fp:n \{0pt\}} should return $-0$, not $+0$.
• The result of $(\pm0) + (\pm0)$, of $x + (-x)$, and of $(-x) + x$ should depend on the rounding mode.
• \texttt{0e9999999999} gives a \texttt{TpX} “number too large” error.
• Subnormals are not implemented.

Possible optimizations/improvements.

• Document that \texttt{l3trial/l3fp-types} introduces tools for adding new types.
• In subsection 9.1, write a grammar.
• It would be nice if the \texttt{parse} auxiliaries for each operation were set up in the corresponding module, rather than centralizing in \texttt{l3fp-parse}.

• Some functions should get an \_\texttt{o} ending to indicate that they expand after their result.

• More care should be given to distinguish expandable/restricted expandable (auxiliary and internal) functions.

• The code for the \texttt{ternary} set of functions is ugly.

• There are many - missing in the doc to avoid bad line-breaks.

• The algorithm for computing the logarithm of the significand could be made to use a 5 terms Taylor series instead of 10 terms by taking $c = 2000/([200x] + 1) \in [10, 95]$ instead of $c \in [1, 10]$. Also, it would then be possible to simplify the computation of $t$. However, we would then have to hard-code the logarithms of 44 small integers instead of 9.

• Improve notations in the explanations of the division algorithm (\texttt{l3fp-basics}).

• Understand and document \texttt{\_\_fp_basics_pack_weird_low:NNNWw} and \texttt{\_\_fp-_ basics_pack_weird_high:NNNNNNNNNNw} better. Move the other \texttt{basics_pack} auxiliaries to \texttt{l3fp-aux} under a better name.

• Find out if underflow can really occur for trigonometric functions, and redoc as appropriate.

• Add bibliography. Some of Kahan’s articles, some previous TeX fp packages, the international standards,

• Also take into account the “inexact” exception?

• Support multi-character prefix operators (e.g., @/ or whatever)?
Part XXIV

The \texttt{l3fparray} package: fast global floating point arrays

1 \texttt{l3fparray} documentation

For applications requiring heavy use of floating points, this module provides arrays which can be accessed in constant time (contrast \texttt{l3seq}, where access time is linear). The interface is very close to that of \texttt{l3intarray}. The size of the array is fixed and must be given at point of initialisation.

\begin{verbatim}
\fparray_new:Nn \fparray_new:Nn \langle \textit{fparray var} \rangle \{\langle \textit{size} \rangle\}
\end{verbatim}

Evaluates the integer expression \(\langle \textit{size} \rangle\) and allocates an \textit{(floating point array variable)} with that number of (zero) entries. The variable name should start with \texttt{\g_} because assignments are always global.

\begin{verbatim}
\fparray_count:N \fparray_count:N \langle \textit{fparray var} \rangle
\end{verbatim}

Expands to the number of entries in the \textit{(floating point array variable)}. This is performed in constant time.

\begin{verbatim}
\fparray_gset:Nnn \fparray_gset:Nnn \langle \textit{fparray var} \rangle \{\langle \textit{position} \rangle\} \{\langle \textit{value} \rangle\}
\end{verbatim}

Stores the result of evaluating the floating point expression \(\langle \textit{value} \rangle\) into the \textit{(floating point array variable)} at the (integer expression) \(\langle \textit{position} \rangle\). If the \(\langle \textit{position} \rangle\) is not between 1 and the \texttt{\fparray_count:N}, an error occurs. Assignments are always global.

\begin{verbatim}
\fparray_gzero:N \fparray_gzero:N \langle \textit{fparray var} \rangle
\end{verbatim}

Sets all entries of the \textit{(floating point array variable)} to \(+0\). Assignments are always global.

\begin{verbatim}
\fparray_item:Nn \fparray_item_to_tl:Nn \langle \textit{fparray var} \rangle \{\langle \textit{position} \rangle\}
\end{verbatim}

Applies \texttt{\fp_use:N} or \texttt{\fp_to_tl:N} (respectively) to the floating point entry stored at the (integer expression) \(\langle \textit{position} \rangle\) in the \textit{(floating point array variable)}. If the \(\langle \textit{position} \rangle\) is not between 1 and the \texttt{\fparray_count:N}, an error occurs.
Part XXV

The \texttt{l3sort} package

Sorting functions

1 Controlling sorting

\LaTeX{} comes with a facility to sort list variables (sequences, token lists, or comma-lists) according to some user-defined comparison. For instance,

\begin{verbatim}
\clist_set:Nn \l_foo_clist { 3 , 01 , -2 , 5 , +1 }
\clist_sort:Nn \l_foo_clist
{ \int_compare:nNnTF { #1 } > { #2 }
{ \sort_return_swapped: }
{ \sort_return_same: }
}
\end{verbatim}

results in \l_foo_clist holding the values \{-2 , 01 , +1 , 3 , 5 \} sorted in non-decreasing order.

The code defining the comparison should call \texttt{\sort_return_swapped:} if the two items given as \#1 and \#2 are not in the correct order, and otherwise it should call \texttt{\sort_return_same:} to indicate that the order of this pair of items should not be changed.

For instance, a \langle \textit{comparison code} \rangle consisting only of \texttt{\sort_return_same:} with no test yields a trivial sort: the final order is identical to the original order. Conversely, using a \langle \textit{comparison code} \rangle consisting only of \texttt{\sort_return_swapped:} reverses the list (in a fairly inefficient way).

\texttt{\LaTeX{}hackers note:} The current implementation is limited to sorting approximately 20000 items (40000 in \LaTeX{}X), depending on what other packages are loaded.

Internally, the code from \texttt{l3sort} stores items in \texttt{\toks} registers allocated locally. Thus, the \langle \textit{comparison code} \rangle should not call \texttt{\newtoks} or other commands that allocate new \texttt{\toks} registers. On the other hand, altering the value of a previously allocated \texttt{\toks} register is not a problem.

\begin{verbatim}
\seq_sort:Nn \langle \textit{seq var} \rangle
{ \sort_return_same: or \sort_return_swapped: ... }
\end{verbatim}

Indicates whether to keep the order or swap the order of two items that are compared in the sorting code. Only one of the \texttt{\sort_return...} functions should be used by the code, according to the results of some tests on the items \#1 and \#2 to be compared.
Part XXVI

The l3tl-analysis package: Analysing token lists

1 l3tl-analysis documentation

This module mostly provides internal functions for use in the l3regex module. However, it provides as a side-effect a user debugging function, very similar to the \ShowTokens macro from the ted package.

\tl_analysis_show:n \{token list\}
Displays to the terminal the detailed decomposition of the ⟨token list⟩ into tokens, showing the category code of each character token, the meaning of control sequences and active characters, and the value of registers.

\tl_analysis_map_inline:nn \{token list\} \{inline function\}
Applies the ⟨inline function⟩ to each individual ⟨token⟩ in the ⟨token list⟩. The ⟨inline function⟩ receives three arguments:

- ⟨tokens⟩, which both o-expand and x-expand to the ⟨token⟩. The detailed form of ⟨token⟩ may change in later releases.
- ⟨char code⟩, a decimal representation of the character code of the token, −1 if it is a control sequence (with ⟨catcode⟩ 0).
- ⟨catcode⟩, a capital hexadecimal digit which denotes the category code of the ⟨token⟩ (0: control sequence, 1: begin-group, 2: end-group, 3: math shift, 4: alignment tab, 6: parameter, 7: superscript, 8: subscript, A: space, B: letter, C:other, D:active).

As all other mappings the mapping is done at the current group level, i.e. any local assignments made by the ⟨inline function⟩ remain in effect after the loop.
The \texttt{l3regex} package: Regular expressions in \TeX

The \texttt{l3regex} package provides regular expression testing, extraction of submatches, splitting, and replacement, all acting on token lists. The syntax of regular expressions is mostly a subset of the \texttt{pcre} syntax (and very close to \texttt{posix}), with some additions due to the fact that \TeX manipulates tokens rather than characters. For performance reasons, only a limited set of features are implemented. Notably, back-references are not supported.

Let us give a few examples. After

\begin{verbatim}
\tl_set:Nn \l_my_tl { That\textcat. }
\regex_replace_once:nnN { at } { is } \l_my_tl
\end{verbatim}

the token list variable \texttt{\l_my_tl} holds the text \textquote{This \textit{cat}.}, where the first occurrence of \textquote{at} was replaced by \textquote{is}. A more complicated example is a pattern to emphasize each word and add a comma after it:

\begin{verbatim}
\regex_replace_all:nnN { \w+ } { \c{emph}\cB\{ \0 \cE\} , } \l_my_tl
\end{verbatim}

The \texttt{\w} sequence represents any \enquote{word} character, and \texttt{+} indicates that the \texttt{\w} sequence should be repeated as many times as possible (at least once), hence matching a word in the input token list. In the replacement text, \texttt{\0} denotes the full match (here, a word). The command \texttt{\emph} is inserted using \texttt{\c{emph}}, and its argument \texttt{\0} is put between braces \texttt{\c{}} and \texttt{\c{}}.

If a regular expression is to be used several times, it can be compiled once, and stored in a regex variable using \texttt{\regex_const:Nn}. For example,

\begin{verbatim}
\regex_const:Nn \c_foo_regex { \c{begin}\cB. (\c[^BE].*) \cE. }
\end{verbatim}

stores in \texttt{\c_foo_regex} a regular expression which matches the starting marker for an environment: \texttt{\begin}, followed by a begin-group token (\texttt{\cB}.), then any number of tokens which are neither begin-group nor end-group character tokens (\texttt{\c[^BE].*}), ending with an end-group token (\texttt{\cE}.). As explained in the next section, the parentheses \enquote{capture} the result of \texttt{\c[^BE].*}, giving us access to the name of the environment when doing replacements.

1 Syntax of regular expressions

We start with a few examples, and encourage the reader to apply \texttt{\regex_show:n} to these regular expressions.

- \texttt{Cat} matches the word \enquote{Cat} capitalized in this way, but also matches the beginning of the word \enquote{Cattle}: use \texttt{\bCat\b} to match a complete word only.

- \texttt{[abc]} matches one letter among \textquote{a}, \textquote{b}, \textquote{c}; the pattern \texttt{(a|b|c)} matches the same three possible letters (but see the discussion of submatches below).

- \texttt{[A-Za-z]*} matches any number (due to the quantifier \texttt{*}) of Latin letters (not accented).
• \c\{A-Z\d[\-\d]\}\* matches a control sequence made of Latin letters.

• _\-[\-\d]*_ matches an underscore, any number of characters other than underscore, and another underscore; it is equivalent to _\.-?_ where . matches arbitrary characters and the lazy quantifier *? means to match as few characters as possible, thus avoiding matching underscores.

• \([\+\-]?)\d+ matches an explicit integer with at most one sign.

• \([\+\-]_\[\-\]_\d+\]* matches an explicit integer with any number of + and – signs, with spaces allowed except within the mantissa, and surrounded by spaces.

• \([\+\-]_\d+\)*\d+\* matches an explicit integer or decimal number; using \[\d\] instead of \ would allow the comma as a decimal marker.

• \([\+\-]_\d+\)*((?i)pt|in|\[cem\]|ex|\[bs\]|\[dn\]|\[pcn\]c)\* matches an explicit dimension with any unit that \TeX{} knows, where (?!i) means to treat lowercase and uppercase letters identically.

• \([\+\-]_\d+\)*((?i)nan|inf|((\d+|\d+\*e\[\+\-]_\d+\]*)\* matches an explicit floating point number or the special values nan and inf (with signs and spaces allowed).

• \([\+\-]_\d+\)*\d+C_.\* matches an explicit integer or control sequence (without checking whether it is an integer variable).

• \G.*?\K at the beginning of a regular expression matches and discards (due to \K) everything between the end of the previous match (\G) and what is matched by the rest of the regular expression; this is useful in \regex_replace_all:nnN when the goal is to extract matches or submatches in a finer way than with \regex_extract_all:nnN.

While it is impossible for a regular expression to match only integer expressions, \([\+\-]_\d+\)*\{\([\+\-]_\d+\)*\} matches among other things all valid integer expressions (made only with explicit integers). One should follow it with further testing.

Most characters match exactly themselves, with an arbitrary category code. Some characters are special and must be escaped with a backslash (e.g., \ matches a star character). Some escape sequences of the form backslash–letter also have a special meaning (for instance \d matches any digit). As a rule,

• every alphanumeric character (A–Z, a–z, 0–9) matches exactly itself, and should not be escaped, because \A, \B, . . . have special meanings;

• non-alphanumeric printable ascii characters can (and should) always be escaped: many of them have special meanings (e.g., use \, \, \, \); spaces should always be escaped (even in character classes);

• any other character may be escaped or not, without any effect: both versions match exactly that character.
Note that these rules play nicely with the fact that many non-alphanumeric characters are
difficult to input into TeX under normal category codes. For instance, \abc\% matches
the characters \abc% (with arbitrary category codes), but does not match the control
sequence \abc followed by a percent character. Matching control sequences can be done
using the \c{⟨regex⟩} syntax (see below).

Any special character which appears at a place where its special behaviour cannot
apply matches itself instead (for instance, a quantifier appearing at the beginning of a
string), after raising a warning.

Characters.

\x{hh...} Character with hex code hh...
\xhh Character with hex code hh.
\a Alarm (hex 07).
\e Escape (hex 1B).
\f Form-feed (hex 0C).
\n New line (hex 0A).
\r Carriage return (hex 0D).
\t Horizontal tab (hex 09).

Character types.
. A single period matches any token.
\d Any decimal digit.
\h Any horizontal space character, equivalent to [ \ \^I]: space and tab.
\s Any space character, equivalent to [ \ \^I\^J\^L\^M].
\v Any vertical space character, equivalent to [ \^J\^K\^L\^M]. Note that \^K
is a vertical space, but not a space, for compatibility with Perl.
\w Any word character, i.e., alphanumerics and underscore, equivalent to the explicit
class [A-Za-z0-9\_].
\D Any token not matched by \d.
\H Any token not matched by \h.
\N Any token other than the \n character (hex 0A).
\S Any token not matched by \s.
\V Any token not matched by \v.
\W Any token not matched by \w.

Of those, . , \D, \H, \M, \S, \W, and \W match arbitrary control sequences.
Character classes match exactly one token in the subject.

[ . . . ] Positive character class. Matches any of the specified tokens.
[^... ]  Negative character class. Matches any token other than the specified characters.

x-y Within a character class, this denotes a range (can be used with escaped characters).

[:⟨name⟩:] Within a character class (one more set of brackets), this denotes the POSIX character class ⟨name⟩, which can be alnum, alpha, ascii, blank, cntrl, digit, graph, lower, print, punct, space, upper, word, or xdigit.

[:¬⟨name⟩:] Negative POSIX character class.

For instance, [a-oq-z\cC.] matches any lowercase latin letter except p, as well as control sequences (see below for a description of \c).

Quantifiers (repetition).

? 0 or 1, greedy.
?? 0 or 1, lazy.
* 0 or more, greedy.
*? 0 or more, lazy.
+ 1 or more, greedy.
+? 1 or more, lazy.
{n} Exactly n.
{n,} n or more, greedy.
{n,}? n or more, lazy.
{n,m} At least n, no more than m, greedy.
{n,m}? At least n, no more than m, lazy.

Anchors and simple assertions.

\b Word boundary: either the previous token is matched by \w and the next by \W, or the opposite. For this purpose, the ends of the token list are considered as \W.

\B Not a word boundary: between two \w tokens or two \W tokens (including the boundary).

^ or \A Start of the subject token list.

\$ or \Z End of the subject token list.

\G Start of the current match. This is only different from ^ in the case of multiple matches: for instance \regex_count:nnNN { \G a } { aaba } \l_tmpa_int yields 2, but replacing \G by ^ would result in \l_tmpa_int holding the value 1.

Alternation and capturing groups.

A|B|C Either one of A, B, or C.

(...) Capturing group.

(?::...) Non-capturing group.
Non-capturing group which resets the group number for capturing groups in each
alternative. The following group is numbered with the first unused group number.

The \c escape sequence allows to test the category code of tokens, and match control
sequences. Each character category is represented by a single uppercase letter:

- C for control sequences;
- B for begin-group tokens;
- E for end-group tokens;
- M for math shift;
- T for alignment tab tokens;
- P for macro parameter tokens;
- U for superscript tokens (up);
- D for subscript tokens (down);
- S for spaces;
- L for letters;
- 0 for others; and
- A for active characters.

The \c escape sequence is used as follows.

- \c\{\regex\} A control sequence whose csname matches the \regex, anchored at the beginning
  and end, so that \c\{\begin\} matches exactly \begin, and nothing else.

- \cX Applies to the next object, which can be a character, character property, class,
or group, and forces this object to only match tokens with category X (any of
CBEMTPUDSLOA). For instance, \cL[A-Z\d] matches uppercase letters and digits of
category code letter, \cC, matches any control sequence, and \cO(abc) matches
abc where each character has category other.

- \c[XYZ] Applies to the next object, and forces it to only match tokens with category X, Y,
or Z (each being any of CBEMTPUDSLOA). For instance, \c[LSO](..) matches two
tokens of category letter, space, or other.

- \c[^XYZ] Applies to the next object and prevents it from matching any token with category
X, Y, or Z (each being any of CBEMTPUDSLOA). For instance, \c[^G]\d matches digits
which have any category different from other.

The category code tests can be used inside classes; for instance, [\cO\d \c[LO][A-F]]
matches what \TeX{} considers as hexadecimal digits, namely digits with category other,
or uppercase letters from A to F with category either letter or other. Within a group
affected by a category code test, the outer test can be overridden by a nested test: for
instance, \cL(ab\cO\*cd) matches ab*cd where all characters are of category letter,
except * which has category other.

The \u escape sequence allows to insert the contents of a token list directly into
a regular expression or a replacement, avoiding the need to escape special characters.
Namely, \u{⟨tl var name⟩} matches the exact contents of the token list ⟨tl var⟩. Within a \c{...} control sequence matching, the \u escape sequence only expands its argument once, in effect performing \tl_to_str:v. Quantifiers are not supported directly: use a group.

The option (?i) makes the match case insensitive (identifying A–Z with a–z; no Unicode support yet). This applies until the end of the group in which it appears, and can be reverted using (?-i). For instance, in (?i)(a(?-i)b|c)d, the letters a and d are affected by the i option. Characters within ranges and classes are affected individually: (?i)[Y–\] is equivalent to [YZ]\[\yz], and (?i)[^aeiou] matches any character which is not a vowel. Neither character properties, nor \c{...} nor \u{...} are affected by the i option.

In character classes, only [, ^, –, ], \ and spaces are special, and should be escaped. Other non-alphanumeric characters can still be escaped without harm. Any escape sequence which matches a single character (\d, \D, etc.) is supported in character classes. If the first character is ^, then the meaning of the character class is inverted; ^ appearing anywhere else in the range is not special. If the first character (possibly following a leading ^) is ] then it does not need to be escaped since ending the range there would make it empty. Ranges of characters can be expressed using –, for instance, [\D 0–5] and [^6–9] are equivalent.

Capturing groups are a means of extracting information about the match. Parenthesized groups are labelled in the order of their opening parenthesis, starting at 1. The contents of those groups corresponding to the “best” match (leftmost longest) can be extracted and stored in a sequence of token lists using for instance \regex_extract_once:nnN { (. \K c)+ \d } { acbc3 } \l_foo_seq results in \l_foo_seq containing the items \{c3\} and \{bc\}: the true match is \{acbc3\}, with first submatch \{bc\}, but \K resets the beginning of the match to the last position where it appears.

2 Syntax of the replacement text

Most of the features described in regular expressions do not make sense within the replacement text. Backslash introduces various special constructions, described further below:

- \0 is the whole match;
- \1 is the submatch that was matched by the first (capturing) group (…); similarly for \2, …, \9 and \g{(number)};
- \u{ } inserts a space (spaces are ignored when not escaped);
• \a, \e, \f, \n, \r, \t; \x{\text{hh}h} correspond to single characters as in regular expressions;
• \c{⟨cs name⟩} inserts a control sequence;
• \c{⟨category⟩⟨character⟩} (see below);
• \u{⟨tl var name⟩} inserts the contents of the ⟨tl var⟩ (see below).

Characters other than backslash and space are simply inserted in the result (but since the replacement text is first converted to a string, one should also escape characters that are special for \TeX, for instance use \#). Non-alphanumeric characters can always be safely escaped with a backslash.

For instance,
\begin{verbatim}
\tl_set:Nn \l_my_tl { Hello,-world! }
\regex_replace_all:nnN { ([er]l|o) . } { (\0--\1) } \l_my_tl
\end{verbatim}
results in \l_my_tl holding H(ell--el)(o,--o) w(or--o)(l--d--l)!

The submatches are numbered according to the order in which the opening parenthesis of capturing groups appear in the regular expression to match. The \n-th submatch is empty if there are fewer than \n capturing groups or for capturing groups that appear in alternatives that were not used for the match. In case a capturing group matches several times during a match (due to quantifiers) only the last match is used in the replacement text. Submatches always keep the same category codes as in the original token list.

The characters inserted by the replacement have category code 12 (other) by default, with the exception of space characters. Spaces inserted through \, have category code 10, while spaces inserted through \x{20} or \x{20} have category code 12. The escape sequence \c allows to insert characters with arbitrary category codes, as well as control sequences.

\cX(...) Produces the characters “…” with category \text{X}, which must be one of \text{CBEMTPUDSLOA} as in regular expressions. Parentheses are optional for a single character (which can be an escape sequence). When nested, the innermost category code applies, for instance \cL{Hello\cS\ world}! gives this text with standard category codes.

\c{⟨text⟩} Produces the control sequence with csname ⟨text⟩. The ⟨text⟩ may contain references to the submatches \0, \1, and so on, as in the example for \u below.

The escape sequence \u{⟨tl var name⟩} allows to insert the contents of the token list with name ⟨tl var name⟩ directly into the replacement, giving an easier control of category codes. When nested in \c{⟨text⟩} and \u{⟨text⟩} constructions, the \u and \c escape sequences perform \tl_to_str:v, namely extract the value of the control sequence and turn it into a string. Matches can also be used within the arguments of \c and \u. For instance,
\begin{verbatim}
\tl_set:Nn \l_my_one_tl { first }
\tl_set:Nn \l_my_two_tl { \emph{second} } \tl_set:Nn \l_my_tl { one , two , one , one }
\regex_replace_all:nnN { ^[^,]+ } { \u{l_my_\0_tl} } \l_my_tl
\end{verbatim}
results in \l_my_tl holding \text{first,\emph{second},first,first}.

228
3 Pre-compiling regular expressions

If a regular expression is to be used several times, it is better to compile it once rather than doing it each time the regular expression is used. The compiled regular expression is stored in a variable. All of the \texttt{l3regex} module’s functions can be given their regular expression argument either as an explicit string or as a compiled regular expression.

\begin{verbatim}
\regex_new:N \l_my_regex
\regex_set:Nn \l_my_regex { my\ (simple\ )\? reg(ular\ expression) }
\end{verbatim}

The assignment is local for \texttt{\regex_set:Nn} and global for \texttt{\regex_gset:Nn}. Use \texttt{\regex_const:Nn} for compiled expressions which never change.

\begin{verbatim}
\regex_show:n \l_my_regex
\regex_show:N \l_my_regex { my\ (simple\ )\? reg(ular\ expression) }
\end{verbatim}

indicating that the anchor \texttt{\A} only applies to the first branch: the second branch is not anchored to the beginning of the match.

4 Matching

All regular expression functions are available in both \texttt{:n} and \texttt{:N} variants. The former require a “standard” regular expression, while the later require a compiled expression as generated by \texttt{\regex_(g)set:Nn}.

\begin{verbatim}
\regex_match:nnTF \l_my_regex \l_token
\regex_match:Nn \l_my_regex \l_token { TRUE } { FALSE }
\end{verbatim}

leaves \texttt{TRUE} then \texttt{FALSE} in the input stream.
Sets \( \text{int var} \) within the current \TeX{} group level equal to the number of times \( \langle \text{regular expression} \rangle \) appears in \( \langle \text{token list} \rangle \). The search starts by finding the left-most longest match, respecting greedy and lazy (non-greedy) operators. Then the search starts again from the character following the last character of the previous match, until reaching the end of the token list. Infinite loops are prevented in the case where the regular expression can match an empty token list: then we count one match between each pair of characters. For instance,

\begin{verbatim}
\int_new:N \l_foo_int
\regex_count:nnN { (b+|c) } { abbabcbbb } \l_foo_int
\end{verbatim}

results in \( \l_foo_int \) taking the value 5.

## 5 Submatch extraction

\begin{verbatim}
\regex_extract_once:nnN { \langle \text{regex} \rangle \} \{ \langle \text{token list} \rangle \} \{ \text{seq var} \}
\regex_extract_once:nnNTF { \langle \text{regex} \rangle \} \{ \langle \text{token list} \rangle \} \{ \text{seq var} \} \{ \langle \text{true code} \rangle \} \{ \langle \text{false code} \rangle \}
\end{verbatim}

Finds the first match of the \( \langle \text{regular expression} \rangle \) in the \( \langle \text{token list} \rangle \). If it exists, the match is stored as the first item of the \( \langle \text{seq var} \rangle \), and further items are the contents of capturing groups, in the order of their opening parenthesis. The \( \langle \text{seq var} \rangle \) is assigned locally. If there is no match, the \( \langle \text{seq var} \rangle \) is cleared. The testing versions insert the \( \langle \text{true code} \rangle \) into the input stream if a match was found, and the \( \langle \text{false code} \rangle \) otherwise. For instance, assume that you type

\begin{verbatim}
\regex_extract_once:nnNTF { \A(La)?TeX(!*)\Z } { LaTeX!!! } \l_foo_seq
{ true } { false }
\end{verbatim}

Then the regular expression (anchored at the start with \( \A \) and at the end with \( \Z \)) must match the whole token list. The first capturing group, \( (La)? \), matches \( La \), and the second capturing group, \( (!*) \), matches \( !!! \). Thus, \( \l_foo_seq \) contains as a result the items \{LaTeX!!!\}, \{La\}, and \{!!!\}, and the \text{true} branch is left in the input stream. Note that the \( n \)-th item of \( \l_foo_seq \), as obtained using \texttt{\seq_item:Nn}, correspond to the submatch numbered \( (n-1) \) in functions such as \texttt{\regex_replace_once:nnN}.

\begin{verbatim}
\regex_extract_all:nnN { \langle \text{regex} \rangle \} \{ \langle \text{token list} \rangle \} \{ \text{seq var} \}
\regex_extract_all:nnNTF { \langle \text{regex} \rangle \} \{ \langle \text{token list} \rangle \} \{ \text{seq var} \} \{ \langle \text{true code} \rangle \} \{ \langle \text{false code} \rangle \}
\end{verbatim}

Finds all matches of the \( \langle \text{regular expression} \rangle \) in the \( \langle \text{token list} \rangle \), and stores all the submatch information in a single sequence (concatenating the results of multiple \texttt{\regex_extract_once:nnN} calls). The \( \langle \text{seq var} \rangle \) is assigned locally. If there is no match, the \( \langle \text{seq var} \rangle \) is cleared. The testing versions insert the \( \langle \text{true code} \rangle \) into the input stream if a match was found, and the \( \langle \text{false code} \rangle \) otherwise. For instance, assume that you type

\begin{verbatim}
\regex_extract_all:nnNTF { \w+ } { Hello,-world! } \l_foo_seq
{ true } { false }
\end{verbatim}

Then the regular expression matches twice, the resulting sequence contains the two items \{Hello\} and \{world\}, and the \text{true} branch is left in the input stream.
Splits the \langle token list \rangle into a sequence of parts, delimited by matches of the \langle regular expression \rangle. If the \langle regular expression \rangle has capturing groups, then the token lists that they match are stored as items of the sequence as well. The assignment to \langle seq var \rangle is local. If no match is found the resulting \langle seq var \rangle has the \langle token list \rangle as its sole item. If the \langle regular expression \rangle matches the empty token list, then the \langle token list \rangle is split into single tokens. The testing versions insert the \langle true code \rangle into the input stream if a match was found, and the \langle false code \rangle otherwise. For example, after
\seq_new:N \l_path_seq
\regex_split:nnNTF { / } { the/path/for/this/file.tex } \l_path_seq
\{ true \} \{ false \}
the sequence \l_path_seq contains the items \{the\}, \{path\}, \{for\}, \{this\}, and \{file.tex\}, and the true branch is left in the input stream.

6 Replacement

Searches for the \langle regular expression \rangle in the \langle token list \rangle and replaces the first match with the \langle replacement \rangle. The result is assigned locally to \langle tl var \rangle. In the \langle replacement \rangle, \0 represents the full match, \1 represent the contents of the first capturing group, \2 of the second, etc.

Replaces all occurrences of the \langle regular expression \rangle in the \langle token list \rangle by the \langle replacement \rangle, where \0 represents the full match, \1 represent the contents of the first capturing group, \2 of the second, etc. Every match is treated independently, and matches cannot overlap. The result is assigned locally to \langle tl var \rangle.

7 Constants and variables

Scratch regex for local assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

Scratch regex for global assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX3-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.
8 Bugs, misfeatures, future work, and other possibilities

The following need to be done now.

- Rewrite the documentation in a more ordered way, perhaps add a BNF?
  Additional error-checking to come.
- Clean up the use of messages.
- Cleaner error reporting in the replacement phase.
- Add tracing information.
- Detect attempts to use back-references and other non-implemented syntax.
- Test for the maximum register \c{max_register:int}.
- Find out whether the fact that \W and friends match the end-marker leads to bugs.
  Possibly update \__regex_item_reverse:n.
- The empty cs should be matched by \c{}, not by \c{csname.endcsname}\s?}.
  Code improvements to come.
- Shift arrays so that the useful information starts at position 1.
- Only build \c{...} once.
- Use arrays for the left and right state stacks when compiling a regex.
- Should \__regex_action_free_group:n only be used for greedy \{n,\} quantifier? (I think not.)
- Quantifiers for \u and assertions.
- When matching, keep track of an explicit stack of current\_state and current\_submatches.
- If possible, when a state is reused by the same thread, kill other subthreads.
- Use an array rather than \l__regex_balance_tl to build the function \_--regex\_replacement\_balance\_one\_match:n.
- Reduce the number of epsilon-transitions in alternatives.
- Optimize simple strings: use less states (abcade should give two states, for abc and ade). [Does that really make sense?]
- Optimize groups with no alternative.
- Optimize states with a single \__regex_action_free:n.
- Optimize the use of \__regex_action_success: by inserting it in state 2 directly instead of having an extra transition.
- Optimize the use of \int_step_... functions.
• Groups don’t capture within regexes for csnames; optimize and document.

• Better “show” for anchors, properties, and catcode tests.

• Does \K really need a new state for itself?

• When compiling, use a boolean in_cs and less magic numbers.

• Instead of checking whether the character is special or alphanumeric using its character code, check if it is special in regexes with \cs_if_exist tests.

The following features are likely to be implemented at some point in the future.

• General look-ahead/behind assertions.

• Regex matching on external files.

• Conditional subpatterns with look ahead/behind: “if what follows is [...] then [...]”.

• (.*.) and (?)..) sequences to set some options.

• UTF-8 mode for pdf\TeX.

• Newline conventions are not done. In particular, we should have an option for . not to match newlines. Also, \A should differ from ^, and \Z, \z and $ should differ.

• Unicode properties: \p{..} and \P{..}: \X which should match any “extended” Unicode sequence. This requires to manipulate a lot of data, probably using tree-boxes.

• Provide a syntax such as \ur{l_my_regex} to use an already-compiled regex in a more complicated regex. This makes regexes more easily composable.

• Allowing \u{l_my_tl} in more places, for instance as the number of repetitions in a quantifier.

• Callout with (?C...) or other syntax: some internal code changes make that possible, and it can be useful for instance in the replacement code to stop a regex replacement when some marker has been found; this raises the question of a potential \regex_break: and then of playing well with \tl_map_break: called from within the code in a regex. It also raises the question of nested calls to the regex machinery, which is a problem since \fontdimen are global.

• Conditional subpatterns (other than with a look-ahead or look-behind condition): this is non-regular, isn’t it?

• Named subpatterns: \TeX programmers have lived so far without any need for named macro parameters.

The following features of \PCRE or Perl may or may not be implemented.

• Back-references: non-regular feature, this requires backtracking, which is prohibitively slow.
• Recursion: this is a non-regular feature.

• Atomic grouping, possessive quantifiers: those tools, mostly meant to fix catastrophic backtracking, are unnecessary in a non-backtracking algorithm, and difficult to implement.

• Subroutine calls: this syntactic sugar is difficult to include in a non-backtracking algorithm, in particular because the corresponding group should be treated as atomic.

• Backtracking control verbs: intrinsically tied to backtracking.

• \ddd, matching the character with octal code ddd: we already have \x{...} and the syntax is confusingly close to what we could have used for backreferences (\1, \2, \ldots), making it harder to produce useful error message.

• \cx, similar to \TeX’s own \~x.

• Comments: \TeX already has its own system for comments.

• \Q...\E escaping: this would require to read the argument verbatim, which is not in the scope of this module.

• \C single byte in UTF-8 mode: \TeX and \luatex serve us characters directly, and splitting those into bytes is tricky, encoding dependent, and most likely not useful anyways.
Part XXVIII

The \texttt{l3box} package

Boxes

There are three kinds of box operations: horizontal mode denoted with prefix \texttt{\hbox}, vertical mode with prefix \texttt{\vbox}, and the generic operations working in both modes with prefix \texttt{\box}.

1 Creating and initialising boxes

\begin{verbatim}
\box_new:N \box_new:c
\box_clear:N \box_clear:c \box_gclear:N \box_gclear:c
\box_clear_new:N \box_clear_new:c \box_gclear_new:N \box_gclear_new:c
\box_set_eq:NN \box_set_eq:NN \box_gset_eq:NN \box_gset_eq:NN
\box_if_exist_p:N \box_if_exist:NTF \box_if_exist:N \box_if_exist:c TFF
\end{verbatim}

\begin{itemize}
\item \texttt{\box_new:N \box_new:c} creates a new \texttt{\hspace} or raises an error if the name is already taken. The declaration is global. The \texttt{\hspace} is initially void.
\item \texttt{\box_clear:N \box_clear:c \box_gclear:N \box_gclear:c} clears the content of the \texttt{\hspace} by setting the box equal to \texttt{\c_empty_box}.
\item \texttt{\box_clear_new:N \box_clear_new:c \box_gclear_new:N \box_gclear_new:c} ensures that the \texttt{\hspace} exists globally by applying \texttt{\box_new:N} if necessary, then applies \texttt{\box_(g)clear:N} to leave the \texttt{\hspace} empty.
\item \texttt{\box_set_eq:NN \box_set_eq:NN \box_gset_eq:NN \box_gset_eq:NN} sets the content of \texttt{\hspace} equal to that of \texttt{\hspace}.
\item \texttt{\box_if_exist_p:N \box_if_exist:NTF \box_if_exist:N \box_if_exist:c TFF} tests whether the \texttt{\hspace} is currently defined. This does not check that the \texttt{\hspace} really is a box.
\end{itemize}

2 Using boxes

\begin{verbatim}
\box_use:N \box_use:c
\end{verbatim}

\begin{itemize}
\item \texttt{\box_use:N \box_use:c} inserts the current content of the \texttt{\hspace} onto the current list for typesetting. An error is raised if the variable does not exist or if it is invalid.
\end{itemize}

\textbf{\TeX\ hackers note:} This is the \TeX\ primitive \texttt{\copy}.

\newpage

235
\box_move_right:nn \box_move_left:nn
This function operates in vertical mode, and inserts the material specified by the \texttt{(box function)} such that its reference point is displaced horizontally by the given \texttt{(dimexpr)} from the reference point for typesetting, to the right or left as appropriate. The \texttt{(box function)} should be a box operation such as \texttt{\box_use:N \<box>} or a “raw” box specification such as \texttt{\vbox:n \{ xyz \}}.

\box_move_up:nn \box_move_down:nn
This function operates in horizontal mode, and inserts the material specified by the \texttt{(box function)} such that its reference point is displaced vertically by the given \texttt{(dimexpr)} from the reference point for typesetting, up or down as appropriate. The \texttt{(box function)} should be a box operation such as \texttt{\box_use:N \<box>} or a “raw” box specification such as \texttt{\vbox:n \{ xyz \}}.

3 Measuring and setting box dimensions

\box_dp:N \box_dp:c
Calculates the depth (below the baseline) of the \texttt{(box)} in a form suitable for use in a \texttt{(dimension expression)}.

\textbf{\TeXhackers note:} This is the \TeX primitive \texttt{\dp}.

\box_ht:N \box_ht:c
Calculates the height (above the baseline) of the \texttt{(box)} in a form suitable for use in a \texttt{(dimension expression)}.

\textbf{\TeXhackers note:} This is the \TeX primitive \texttt{\ht}.

\box_wd:N \box_wd:c
Calculates the width of the \texttt{(box)} in a form suitable for use in a \texttt{(dimension expression)}.

\textbf{\TeXhackers note:} This is the \TeX primitive \texttt{\wd}.

\box_set_dp:Nn \box_set_dp:cn \box_gset_dp:Nn \box_gset_dp:cn
Set the depth (below the baseline) of the \texttt{(box)} to the value of the \texttt{(dimension expression)}.

\textbf{Updated: 2019-01-22}

\box_set_ht:Nn \box_set_ht:cn \box_gset_ht:Nn \box_gset_ht:cn
Set the height (above the baseline) of the \texttt{(box)} to the value of the \texttt{(dimension expression)}.

\textbf{Updated: 2019-01-22}
\texttt{\box_set_wd:Nn} \texttt{(box) \{dimension expression\}}

Set the width of the \texttt{\langle box\rangle} to the value of the \texttt{\{dimension expression\}}.

\texttt{\box_set_wd:cn} \texttt{\box_gset_wd:Nn} \texttt{\box_gset_wd:cn}

Updated: 2019-01-22

4 Box conditionals

\texttt{\box_if_empty_p:N} \texttt{\box_if_empty_p:c}
\texttt{\box_if_empty:NTF} \texttt{\box_if_empty:cTF}

Tests if \texttt{(box)} is an empty (equal to \texttt{c_empty_box}).

\texttt{\box_if_horizontal_p:N} \texttt{\box_if_horizontal_p:c}
\texttt{\box_if_horizontal:NTF} \texttt{\box_if_horizontal:cTF}

Tests if \texttt{(box)} is a horizontal box.

\texttt{\box_if_vertical_p:N} \texttt{\box_if_vertical_p:c}
\texttt{\box_if_vertical:NTF} \texttt{\box_if_vertical:cTF}

Tests if \texttt{(box)} is a vertical box.

5 The last box inserted

\texttt{\box_set_to_last:N} \texttt{\box_set_to_last:c}
\texttt{\box_gset_to_last:N} \texttt{\box_gset_to_last:c}

Sets the \texttt{\langle box\rangle} equal to the last item (box) added to the current partial list, removing the item from the list at the same time. When applied to the main vertical list, the \texttt{\langle box\rangle} is always void as it is not possible to recover the last added item.

6 Constant boxes

\texttt{\c_empty_box}

This is a permanently empty box, which is neither set as horizontal nor vertical.

\texttt{\TeXhackers note}: At the \TeX level this is a void box.
7 Scratch boxes

Scratch boxes for local assignment. These are never used by the kernel code, and so are safe for use with any \texttt{LATeX3}-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

\l_tmpa_box
\l_tmpb_box

Scratch boxes for global assignment. These are never used by the kernel code, and so are safe for use with any \texttt{LATeX3}-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

8 Viewing box contents

\box_show:N {\box}
\box_show:c

Shows full details of the content of the \texttt{\box} in the terminal.

\box_show:Nnn {\box} {\intexpr_1} {\intexpr_2}
\box_show:cnn

Display the contents of \texttt{\box} in the terminal, showing the first \texttt{\intexpr_1} items of the box, and descending into \texttt{\intexpr_2} group levels.

\box_log:N {\box}
\box_log:c

Writes full details of the content of the \texttt{\box} to the log.

\box_log:Nnn {\box} {\intexpr_1} {\intexpr_2}
\box_log:cnn

Writes the contents of \texttt{\box} to the log, showing the first \texttt{\intexpr_1} items of the box, and descending into \texttt{\intexpr_2} group levels.

9 Boxes and color

All \texttt{LATeX3} boxes are “color safe”: a color set inside the box stops applying after the end of the box has occurred.

10 Horizontal mode boxes

\hbox:n {\contents}

Typesets the \texttt{\contents} into a horizontal box of natural width and then includes this box in the current list for typesetting.
\texttt{\texttt{hbox\_to\_wd:nn}}
\begin{verbatim}
\hbox_to_wd:nn \{\dimexpr\} \{\contents\}
\end{verbatim}
Typesets the \texttt{\contents} into a horizontal box of width \texttt{\dimexpr} and then includes this box in the current list for typesetting.

\texttt{\texttt{hbox\_to\_zero:n}}
\begin{verbatim}
\hbox_to_zero:n \{\contents\}
\end{verbatim}
Typesets the \texttt{\contents} into a horizontal box of zero width and then includes this box in the current list for typesetting.

\texttt{\texttt{hbox\_set:Nn}}
\begin{verbatim}
\hbox_set:Nn \hbox_set:cn \hbox_gset:Nn \hbox_gset:cn
\end{verbatim}
Typesets the \texttt{\contents} at natural width and then stores the result inside the \texttt{\box}.

\texttt{\texttt{hbox\_set\_to\_wd:Nnn}}
\begin{verbatim}
\hbox_set_to_wd:Nnn \{\dimexpr\} \{\contents\}
\end{verbatim}
Typesets the \texttt{\contents} to the width given by the \texttt{\dimexpr} and then stores the result inside the \texttt{\box}.

\texttt{\texttt{hbox\_overlap\_right:n}}
\begin{verbatim}
\hbox_overlap_right:n \{\contents\}
\end{verbatim}
Typesets the \texttt{\contents} into a horizontal box of zero width such that material protrudes to the right of the insertion point.

\texttt{\texttt{hbox\_overlap\_left:n}}
\begin{verbatim}
\hbox_overlap_left:n \{\contents\}
\end{verbatim}
Typesets the \texttt{\contents} into a horizontal box of zero width such that material protrudes to the left of the insertion point.

\texttt{\texttt{hbox\_set:Nw}}
\begin{verbatim}
\hbox_set:Nw \hbox_set:cw \hbox_set_end:
\hbox_gset:Nw \hbox_gset:cw \hbox_gset_end:
\end{verbatim}
Typesets the \texttt{\contents} at natural width and then stores the result inside the \texttt{\box}. In contrast to \texttt{\hbox\_set\_to\_wd:Nnn} this function does not absorb the argument when finding the \texttt{\content}, and so can be used in circumstances where the \texttt{\content} may not be a simple argument.

\texttt{\texttt{hbox\_set\_to\_wd:Nnw}}
\begin{verbatim}
\hbox_set_to_wd:Nnw \{\dimexpr\} \{\contents\} \hbox_set_end:
\end{verbatim}
Typesets the \texttt{\contents} to the width given by the \texttt{\dimexpr} and then stores the result inside the \texttt{\box}. In contrast to \texttt{\hbox\_set\_to\_wd:Nnn} this function does not absorb the argument when finding the \texttt{\content}, and so can be used in circumstances where the \texttt{\content} may not be a simple argument.

\texttt{\texttt{hbox\_unpack:N}}
\begin{verbatim}
\hbox_unpack:N \hbox_unpack:c
\end{verbatim}
Unpacks the content of the horizontal \texttt{\box}, retaining any stretching or shrinking applied when the \texttt{\box} was set.

\textbf{\texttt{\TeX}hackers note:} This is the \TeX primitive \texttt{\unhcopy}.  

239
11 Vertical mode boxes

Vertical boxes inherit their baseline from their contents. The standard case is that the baseline of the box is at the same position as that of the last item added to the box. This means that the box has no depth unless the last item added to it had depth. As a result most vertical boxes have a large height value and small or zero depth. The exception are _top boxes, where the reference point is that of the first item added. These tend to have a large depth and small height, although the latter is typically non-zero.

\vbox:n \{⟨contents⟩\}

Typesets the ⟨contents⟩ into a vertical box of natural height and includes this box in the current list for typesetting.

\vbox_top:n \{⟨contents⟩\}

Typesets the ⟨contents⟩ into a vertical box of natural height and includes this box in the current list for typesetting. The baseline of the box is equal to that of the first item added to the box.

\vbox_to_ht:nn \{⟨dimexpr⟩\} \{⟨contents⟩\}

Typesets the ⟨contents⟩ to the height given by the ⟨dimexpr⟩ and then stores the result inside the ⟨box⟩.

\vbox_to_zero:n \{⟨contents⟩\}

Typesets the ⟨contents⟩ into a vertical box of zero height and then includes this box in the current list for typesetting.

\vbox_set:Nn \langle box \rangle \{⟨contents⟩\}

Typesets the ⟨contents⟩ at natural height and then stores the result inside the ⟨box⟩. The baseline of the box is equal to that of the first item added to the box.

\vbox_set_top:Nn \langle box \rangle \{⟨contents⟩\}

Typesets the ⟨contents⟩ at natural height and then stores the result inside the ⟨box⟩. The baseline of the box is equal to that of the first item added to the box.
Typesets the \langle contents \rangle at natural height and then stores the result inside the \langle box \rangle. In contrast to \vbox_set:Nn this function does not absorb the argument when finding the \langle content \rangle, and so can be used in circumstances where the \langle content \rangle may not be a simple argument.

\vbox_set_to_ht:Nnw \langle box \rangle \{(dimexpr)\} \langle contents \rangle \vbox_set_end:

Typesets the \langle contents \rangle to the height given by the \langle dimexpr \rangle and then stores the result inside the \langle box \rangle. In contrast to \vbox_set_to_ht:Nnn this function does not absorb the argument when finding the \langle content \rangle, and so can be used in circumstances where the \langle content \rangle may not be a simple argument.

Sets \langle box_1 \rangle to contain material to the height given by the \langle dimexpr \rangle by removing content from the top of \langle box_2 \rangle (which must be a vertical box).

Unpacks the content of the vertical \langle box \rangle, retaining any stretching or shrinking applied when the \langle box \rangle was set.

\TeXhackers\ short\ note: This is the \TeX\ primitive \texttt{\unvcopy}.

\section{Using boxes efficiently}

The functions above for using box contents work in exactly the same way as for any other expl3 variable. However, for efficiency reasons, it is also useful to have functions which \texttt{drop} box contents on use. When a box is dropped, the box becomes empty at the group level \texttt{where the box was originally set} rather than necessarily \texttt{at the current group level}.

For example, with

\begin{verbatim}
\hbox_set:Nn \l_tmpa_box \{ A \}
\group_begin:
\hbox_set:Nn \l_tmpa_box \{ B \}
\group_begin:
\box_use_drop:N \l_tmpa_box
\group_end:
\box_show:N \l_tmpa_box
\group_end:
\box_show:N \l_tmpa_box
\end{verbatim}

\section{texlive}
the first use of \texttt{\box_show:N} will show an entirely cleared (void) box, and the second will show the letter A in the box.

These functions should be preferred when the content of the box is no longer required after use. Note that due to the unusual scoping behaviour of \texttt{drop} functions they may be applied to both local and global boxes: the latter will naturally be set and thus cleared at a global level.

\begin{verbatim}
\box_use_drop:N \box_use_drop:c
\end{verbatim}

Inserts the current content of the \texttt{(box)} onto the current list for typesetting then drops the box content. An error is raised if the variable does not exist or if it is invalid. This function may be applied to local or global boxes.

\textbf{TeXhackers note:} This is the \texttt{\box} primitive.

\begin{verbatim}
\box_set_eq_drop:NN \box_set_eq_drop:(cN|Nc|cc)
\end{verbatim}

\begin{verbatim}
\box_gset_eq_drop:NN \box_gset_eq_drop:(cN|Nc|cc)
\end{verbatim}

\begin{verbatim}
\hbox_unpack_drop:N \hbox_unpack_drop:c
\end{verbatim}

\begin{verbatim}
\vbox_unpack_drop:N \vbox_unpack_drop:c
\end{verbatim}

13 \textbf{Affine transformations}

Affine transformations are changes which (informally) preserve straight lines. Simple translations are affine transformations, but are better handled in \TeX{} by doing the translation first, then inserting an unmodified box. On the other hand, rotation and resizing of boxed material can best be handled by modifying boxes. These transformations are described here.
Resizes the ⟨box⟩ to fit within the given ⟨x-size⟩ (horizontally) and ⟨y-size⟩ (vertically); both of the sizes are dimension expressions. The ⟨y-size⟩ is the height only: it does not include any depth. The updated ⟨box⟩ is an hbox, irrespective of the nature of the ⟨box⟩ before the resizing is applied. The final size of the ⟨box⟩ is the smaller of {⟨x-size⟩} and {⟨y-size⟩}, i.e., the result fits within the dimensions specified. Negative sizes cause the material in the ⟨box⟩ to be reversed in direction, but the reference point of the ⟨box⟩ is unchanged. Thus a negative ⟨y-size⟩ results in the ⟨box⟩ having a depth dependent on the height of the original and vice versa.

Resizes the ⟨box⟩ to fit within the given ⟨x-size⟩ (horizontally) and ⟨y-size⟩ (vertically); both of the sizes are dimension expressions. The ⟨y-size⟩ is the total vertical size (height plus depth). The updated ⟨box⟩ is an hbox, irrespective of the nature of the ⟨box⟩ before the resizing is applied. The final size of the ⟨box⟩ is the smaller of {⟨x-size⟩} and {⟨y-size⟩}, i.e., the result fits within the dimensions specified. Negative sizes cause the material in the ⟨box⟩ to be reversed in direction, but the reference point of the ⟨box⟩ is unchanged. Thus a negative ⟨y-size⟩ results in the ⟨box⟩ having a depth dependent on the height of the original and vice versa.

Resizes the ⟨box⟩ to ⟨y-size⟩ (vertically), scaling the horizontal size by the same amount; ⟨y-size⟩ is a dimension expression. The ⟨y-size⟩ is the height only: it does not include any depth. The updated ⟨box⟩ is an hbox, irrespective of the nature of the ⟨box⟩ before the resizing is applied. A negative ⟨y-size⟩ causes the material in the ⟨box⟩ to be reversed in direction, but the reference point of the ⟨box⟩ is unchanged. Thus a negative ⟨y-size⟩ results in the ⟨box⟩ having a depth dependent on the height of the original and vice versa.
Resizes the \( \langle \text{box} \rangle \) to \( \langle y\text{-size} \rangle \) (vertically), scaling the horizontal size by the same amount: \( \langle y\text{-size} \rangle \) is a dimension expression. The \( \langle y\text{-size} \rangle \) is the total vertical size (height plus depth). The updated \( \langle \text{box} \rangle \) is an \texttt{hbox}, irrespective of the nature of the \( \langle \text{box} \rangle \) before the resizing is applied. A negative \( \langle y\text{-size} \rangle \) causes the material in the \( \langle \text{box} \rangle \) to be reversed in direction, but the reference point of the \( \langle \text{box} \rangle \) is unchanged. Thus a negative \( \langle y\text{-size} \rangle \) results in the \( \langle \text{box} \rangle \) having a depth dependent on the height of the original and \textit{vice versa}.

Resizes the \( \langle \text{box} \rangle \) to \( \langle x\text{-size} \rangle \) (horizontally), scaling the vertical size by the same amount: \( \langle x\text{-size} \rangle \) is a dimension expression. The updated \( \langle \text{box} \rangle \) is an \texttt{hbox}, irrespective of the nature of the \( \langle \text{box} \rangle \) before the resizing is applied. A negative \( \langle x\text{-size} \rangle \) causes the material in the \( \langle \text{box} \rangle \) to be reversed in direction, but the reference point of the \( \langle \text{box} \rangle \) is unchanged. Thus a negative \( \langle x\text{-size} \rangle \) results in the \( \langle \text{box} \rangle \) having a depth dependent on the height of the original and \textit{vice versa}.

Resizes the \( \langle \text{box} \rangle \) to \( \langle x\text{-size} \rangle \) (horizontally) and \( \langle y\text{-size} \rangle \) (vertically): both of the sizes are dimension expressions. The \( \langle y\text{-size} \rangle \) is the height only and does not include any depth. The updated \( \langle \text{box} \rangle \) is an \texttt{hbox}, irrespective of the nature of the \( \langle \text{box} \rangle \) before the resizing is applied. Negative sizes cause the material in the \( \langle \text{box} \rangle \) to be reversed in direction, but the reference point of the \( \langle \text{box} \rangle \) is unchanged. Thus a negative \( \langle y\text{-size} \rangle \) results in the \( \langle \text{box} \rangle \) having a depth dependent on the height of the original and \textit{vice versa}.

Resizes the \( \langle \text{box} \rangle \) to \( \langle x\text{-size} \rangle \) (horizontally) and \( \langle y\text{-size} \rangle \) (vertically): both of the sizes are dimension expressions. The \( \langle y\text{-size} \rangle \) is the total vertical size (height plus depth). The updated \( \langle \text{box} \rangle \) is an \texttt{hbox}, irrespective of the nature of the \( \langle \text{box} \rangle \) before the resizing is applied. Negative sizes cause the material in the \( \langle \text{box} \rangle \) to be reversed in direction, but the reference point of the \( \langle \text{box} \rangle \) is unchanged. Thus a negative \( \langle y\text{-size} \rangle \) results in the \( \langle \text{box} \rangle \) having a depth dependent on the height of the original and \textit{vice versa}.
\texttt{\textbackslash box\_rotate:NN} \texttt{\textbackslash box\_rotate:cn} \texttt{\textbackslash box\_grotate:NN} \texttt{\textbackslash box\_grotate:cn} \texttt{Updated: 2019-01-22} \texttt{\box\_rotate:Nn} \texttt{\textbackslash box\_rotate:cn} \texttt{\box\_grotate:Nn} \texttt{\textbackslash box\_grotate:cn} \texttt{Updated: 2019-01-22} \texttt{\box\_scale:Nnn} \texttt{\textbackslash box\_scale:cn} \texttt{\box\_gscale:Nnn} \texttt{\textbackslash box\_gscale:cn} \texttt{Updated: 2019-01-22}

Rotates the ⟨box⟩ by ⟨angle⟩ (in degrees) anti-clockwise about its reference point. The reference point of the updated box is moved horizontally such that it is at the left side of the smallest rectangle enclosing the rotated material. The updated ⟨box⟩ is an hbox, irrespective of the nature of the ⟨box⟩ before the rotation is applied.

Scales the ⟨box⟩ by factors ⟨x-scale⟩ and ⟨y-scale⟩ in the horizontal and vertical directions, respectively (both scales are integer expressions). The updated ⟨box⟩ is an hbox, irrespective of the nature of the ⟨box⟩ before the scaling is applied. Negative scalings cause the material in the ⟨box⟩ to be reversed in direction, but the reference point of the ⟨box⟩ is unchanged. Thus a negative ⟨y-scale⟩ results in the ⟨box⟩ having a depth dependent on the height of the original and 	extit{vice versa}.

14 Primitive box conditionals

\texttt{\textbackslash if\_hbox:N} \texttt{\textbackslash if\_hbox:N (box)} \texttt{\textbackslash else:} \texttt{\textbackslash false code} \texttt{\fi:} Tests is ⟨box⟩ is a horizontal box.

\textbf{\texttt{\textsc{T}\textsc{e}\textsc{x}hacker\textsc{s} note:}} This is the \texttt{\textsc{T}\textsc{e}\textsc{x}} primitive \texttt{\textbackslash ifhbox}.

\texttt{\textbackslash if\_vbox:N} \texttt{\textbackslash if\_vbox:N (box)} \texttt{\textbackslash else:} \texttt{\textbackslash false code} \texttt{\fi:} Tests is ⟨box⟩ is a vertical box.

\textbf{\texttt{\textsc{T}\textsc{e}\textsc{x}hacker\textsc{s} note:}} This is the \texttt{\textsc{T}\textsc{e}\textsc{x}} primitive \texttt{\textbackslash ifvbox}.

\texttt{\textbackslash if\_box\_empty:N} \texttt{\textbackslash if\_box\_empty:N (box)} \texttt{\textbackslash else:} \texttt{\textbackslash false code} \texttt{\fi:} Tests is ⟨box⟩ is an empty (void) box.

\textbf{\texttt{\textsc{T}\textsc{e}\textsc{x}hacker\textsc{s} note:}} This is the \texttt{\textsc{T}\textsc{e}\textsc{x}} primitive \texttt{\textbackslash ifvoid}.
Part XXIX
The \texttt{li3coffins} package
Coffin code layer

The material in this module provides the low-level support system for coffins. For details about the design concept of a coffin, see the \texttt{xcoffins} module (in the \texttt{li3experimental} bundle).

1 Creating and initialising coffins

\begin{verbatim}
\coffin_new:N \coffin_new:c
\coffin_clear:N \coffin_clear:c \coffin_gclear:N \coffin_gclear:c
\coffin_set_eq:NN \coffin_set_eq:Nn \coffin_set_eq:cn \coffin_gset_eq:NN \coffin_gset_eq:cn
\coffin_if_exist_p:N \coffin_if_exist:NTF \coffin_if_exist:p \coffin_if_exist:N \coffin_if_exist:TF \coffin_if_exist:c
\end{verbatim}

\texttt{\coffin_new:N} \texttt{\coffin_new:c}

Creates a new \texttt{\langle coffin \rangle} or raises an error if the name is already taken. The declaration is global. The \texttt{\langle coffin \rangle} is initially empty.

\texttt{\coffin_clear:N} \texttt{\coffin_clear:c} \texttt{\coffin_gclear:N} \texttt{\coffin_gclear:c}

Clears the content of the \texttt{\langle coffin \rangle}.

\texttt{\coffin_set_eq:NN} \texttt{\coffin_set_eq:Nn} \texttt{\coffin_set_eq:cn} \texttt{\coffin_gset_eq:NN} \texttt{\coffin_gset_eq:cn}

Sets both the content and poles of \texttt{\langle coffin\textsubscript{1} \rangle} equal to those of \texttt{\langle coffin\textsubscript{2} \rangle}.

\texttt{\coffin_if_exist_p:N} \texttt{\coffin_if_exist:NTF} \texttt{\coffin_if_exist:p} \texttt{\coffin_if_exist:N} \texttt{\coffin_if_exist:TF} \texttt{\coffin_if_exist:c}

Tests whether the \texttt{\langle coffin \rangle} is currently defined.

2 Setting coffin content and poles

\begin{verbatim}
\hcoffin_set:Nn \hcoffin_set:cn \hcoffin_gset:Nn \hcoffin_gset:cn
\hcoffin_if_exist_p:N \hcoffin_if_exist:NTF \hcoffin_if_exist:p \hcoffin_if_exist:N \hcoffin_if_exist:TF \hcoffin_if_exist:c
\end{verbatim}

\texttt{\hcoffin_set:Nn} \texttt{\hcoffin_set:cn} \texttt{\hcoffin_gset:Nn} \texttt{\hcoffin_gset:cn}

Typesets the \texttt{\langle material \rangle} in horizontal mode, storing the result in the \texttt{\langle coffin \rangle}. The standard poles for the \texttt{\langle coffin \rangle} are then set up based on the size of the typeset material.
\hcoffin_set:Nw \hcoffin_set:cw \hcoffin_set_end:
Typesets the \langle material \rangle in horizontal mode, storing the result in the \langle coffin \rangle. The standard poles for the \langle coffin \rangle are then set up based on the size of the typeset material. These functions are useful for setting the entire contents of an environment in a coffin.

\vcoffin_set:Nnn \vcoffin_set:cnn \vcoffin_gset:Nnn \vcoffin_gset:cnn
Typesets the \langle material \rangle in vertical mode constrained to the given \langle width \rangle and stores the result in the \langle coffin \rangle. The standard poles for the \langle coffin \rangle are then set up based on the size of the typeset material.

\coffin_set_horizontal_pole:Nnn \coffin_set_horizontal_pole:cnn \coffin_gset_horizontal_pole:Nnn \coffin_gset_horizontal_pole:cnn
Sets the \langle pole \rangle to run horizontally through the \langle coffin \rangle. The \langle pole \rangle is placed at the \langle offset \rangle from the bottom edge of the bounding box of the \langle coffin \rangle. The \langle offset \rangle should be given as a dimension expression.

\coffin_set_vertical_pole:Nnn \coffin_set_vertical_pole:cnn \coffin_gset_vertical_pole:Nnn \coffin_gset_vertical_pole:cnn
Sets the \langle pole \rangle to run vertically through the \langle coffin \rangle. The \langle pole \rangle is placed at the \langle offset \rangle from the left-hand edge of the bounding box of the \langle coffin \rangle. The \langle offset \rangle should be given as a dimension expression.
3  Coffin affine transformations

\coffin_resize:Nnn \coffin_resize:cnn \coffin_gresize:Nnn \coffin_gresize:cnn

Resized the \coffin to \width and \totalheight, both of which should be given as dimension expressions.

\coffin_rotate:Nnn \coffin_rotate:cn \coffin_grotate:Nnn \coffin_grotate:cn

Rotates the \coffin by the given \angle (given in degrees counter-clockwise). This process rotates both the coffin content and poles. Multiple rotations do not result in the bounding box of the coffin growing unnecessarily.

\coffin_scale:Nnn \coffin_scale:cn \coffin_gscale:Nnn \coffin_gscale:cn

Scales the \coffin by a factors \xscale and \yscale in the horizontal and vertical directions, respectively. The two scale factors should be given as real numbers.

4  Joining and using coffins

\coffin_attach:Nnn\cn\n\coffin_attach:{\cn\n\coffin_gattach:Nnn\cn\n\coffin_gattach:{\cn\n
This function attaches \coffin2 to \coffin1 such that the bounding box of \coffin1 is not altered, i.e. \coffin2 can protrude outside of the bounding box of the coffin. The alignment is carried out by first calculating \handle1, the point of intersection of \coffin1-pole1 and \coffin1-pole2, and \handle2, the point of intersection of \coffin2-pole1 and \coffin2-pole2. \coffin2 is then attached to \coffin1 such that the relationship between \handle1 and \handle2 is described by the \xoffset and \yoffset. The two offsets should be given as dimension expressions.

\coffin_join:Nnn\cn\n\coffin_join:{\cn\n\coffin_gjoin:Nnn\cn\n\coffin_gjoin:{\cn\n
This function joins \coffin2 to \coffin1 such that the bounding box of \coffin1 may expand. The new bounding box covers the area containing the bounding boxes of the two original coffins. The alignment is carried out by first calculating \handle1, the point of intersection of \coffin1-pole1 and \coffin1-pole2, and \handle2, the point of intersection of \coffin2-pole1 and \coffin2-pole2. \coffin2 is then attached to \coffin1 such that the relationship between \handle1 and \handle2 is described by the \xoffset and \yoffset. The two offsets should be given as dimension expressions.
Typesetting is carried out by first calculating the point of intersection of pole 1 and pole 2. The coffin is then typeset in horizontal mode such that the relationship between the current reference point in the document and the handle is described by the \langle x-offset \rangle and \langle y-offset \rangle. The two offsets should be given as dimension expressions. Typesetting a coffin is therefore analogous to carrying out an alignment where the “parent” coffin is the current insertion point.

5 Measuring coffins

\coffin_dp:N \langle \coffin \rangle \langle \text{color} \rangle
\coffin_dp:N \langle \coffin \rangle
Calculates the depth (below the baseline) of the \langle \coffin \rangle in a form suitable for use in a \langle \text{dimension expression} \rangle.

\coffin_ht:N \langle \coffin \rangle \langle \text{color} \rangle
\coffin_ht:N \langle \coffin \rangle
Calculates the height (above the baseline) of the \langle \coffin \rangle in a form suitable for use in a \langle \text{dimension expression} \rangle.

\coffin_wd:N \langle \coffin \rangle \langle \text{color} \rangle
\coffin_wd:N \langle \coffin \rangle
Calculates the width of the \langle \coffin \rangle in a form suitable for use in a \langle \text{dimension expression} \rangle.

6 Coffin diagnostics

\coffin_display_handles:Nn \langle \coffin \rangle \langle \text{color} \rangle
\coffin_display_handles:Nn \langle \coffin \rangle
This function first calculates the intersections between all of the \langle poles \rangle of the \langle coffin \rangle to give a set of \langle handles \rangle. It then prints the \langle coffin \rangle at the current location in the source, with the position of the \langle handles \rangle marked on the coffin. The \langle handles \rangle are labelled as part of this process: the locations of the \langle handles \rangle and the labels are both printed in the \langle color \rangle specified.

\coffin_mark_handle:Nnnn \langle \coffin \rangle \langle \text{color} \rangle
\coffin_mark_handle:Nnnn \langle \coffin \rangle \langle \text{color} \rangle
This function first calculates the \langle handle \rangle for the \langle coffin \rangle as defined by the intersection of \langle pole1 \rangle and \langle pole2 \rangle. It then marks the position of the \langle handle \rangle on the \langle coffin \rangle. The \langle handle \rangle are labelled as part of this process: the location of the \langle handle \rangle and the label are both printed in the \langle color \rangle specified.

\coffin_show_structure:N \langle \coffin \rangle \langle \text{color} \rangle
\coffin_show_structure:N \langle \coffin \rangle
This function shows the structural information about the \langle coffin \rangle in the terminal. The width, height and depth of the typeset material are given, along with the location of all of the poles of the coffin.

Notice that the poles of a coffin are defined by four values: the \text{x} and \text{y} co-ordinates of a point that the pole passes through and the \text{x}- and \text{y}-components of a vector denoting the direction of the pole. It is the ratio between the later, rather than the absolute values, which determines the direction of the pole.

249
This function writes the structural information about the \texttt{coffin} in the log file. See also \texttt{coffin\_show\_structure:N} which displays the result in the terminal.

7 Constants and variables

A permanently empty coffin.

Scratch coffins for local assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.

Scratch coffins for global assignment. These are never used by the kernel code, and so are safe for use with any \LaTeX-defined function. However, they may be overwritten by other non-kernel code and so should only be used for short-term storage.
Part XXX

The \texttt{l3color-base} package

Color support

This module provides support for color in \LaTeXe. At present, the material here is mainly intended to support a small number of low-level requirements in other \texttt{l3kernel} modules.

1 Color in boxes

Controlling the color of text in boxes requires a small number of control functions, so that the boxed material uses the color at the point where it is set, rather than where it is used.

\begin{verbatim}
\begin{color_group}
...
\end{color_group}
\end{verbatim}

Creates a color group: one used to “trap” color settings.

\begin{verbatim}
\begin{color_group}
\color_group
...
\end{color_group}
\end{verbatim}

Ensures that material inside a box uses the foreground color at the point where the box is set, rather than that in force when the box is used. This function should usually be used within a \begin{color_group}: \ldots \end{color_group} group.

251
Part XXXI

The l3luatex package:
LuaTEX-specific functions

The LuaTEX engine provides access to the Lua programming language, and with it access to the “internals” of \TeX. In order to use this within the framework provided here, a family of functions is available. When used with pdfTEX, pTEX, upTEX or XeTEX these raise an error: use `\sys_if_engine_luatex:T` to avoid this. Details on using Lua with the LuaTEX engine are given in the LuaTEX manual.

1 Breaking out to Lua

\lua_now:n \langle token list \rangle

The \langle token list \rangle is first tokenized by \TeX, which includes converting line ends to spaces in the usual \TeX manner and which respects currently-applicable \TeX category codes. The resulting \langle Lua input \rangle is passed to the Lua interpreter for processing. Each \lua_now:n block is treated by Lua as a separate chunk. The Lua interpreter executes the \langle Lua input \rangle immediately, and in an expandable manner.

\TeXhackers note: \lua_now:e is a macro wrapper around \directlua: when LuaTEX is in use two expansions are required to yield the result of the Lua code.

\lua_shipout:n \langle token list \rangle

The \langle token list \rangle is first tokenized by \TeX, which includes converting line ends to spaces in the usual \TeX manner and which respects currently-applicable \TeX category codes. The resulting \langle Lua input \rangle is passed to the Lua interpreter when the current page is finalised (i.e. at shipout). Each \lua_shipout:n block is treated by Lua as a separate chunk. The Lua interpreter will execute the \langle Lua input \rangle during the page-building routine: no \TeX expansion of the \langle Lua input \rangle will occur at this stage.

In the case of the \lua_shipout_e:n version the input is fully expanded by \TeX in an e-type manner during the shipout operation.

\TeXhackers note: At a \TeX level, the \langle Lua input \rangle is stored as a “whatsit”.

\lua_escape:n \langle token list \rangle

Converts the \langle token list \rangle such that it can safely be passed to Lua: embedded backslashes, double and single quotes, and newlines and carriage returns are escaped. This is done by prepending an extra token consisting of a backslash with category code 12, and for the line endings, converting them to \n and \r, respectively.

\TeXhackers note: \lua_escape:e is a macro wrapper around \luaescapestring: when LuaTEX is in use two expansions are required to yield the result of the Lua code.
2 Lua interfaces

As well as interfaces for \( \LaTeX \), there are a small number of Lua functions provided here.

- **l3kernel**
  All public interfaces provided by the module are stored within the \texttt{l3kernel} table.

- **l3kernel.charcat\((\texttt{charcode}), (\texttt{catcode})\)**
  Constructs a character of \(\texttt{charcode}\) and \(\texttt{catcode}\) and returns the result to \( \LaTeX \).

- **l3kernel.elapsedtime()**
  Returns the CPU time in \( \textit{scaled seconds} \) since the start of the \( \LaTeX \) run or since \texttt{l3kernel.resettimer} was issued. This only measures the time used by the CPU, not the real time, e.g., waiting for user input.

- **l3kernel.filedump\((\texttt{file}), (\texttt{offset}), (\texttt{length})\)**
  Returns the uppercase hexadecimal representation of the content of the \(\texttt{file}\) read as bytes. If the \(\texttt{length}\) is given, only this part of the file is returned; similarly, one may specify the \(\texttt{offset}\) from the start of the file. If the \(\texttt{length}\) is not given, the entire file is read starting at the \(\texttt{offset}\).

- **l3kernel.filemdfivesum\((\texttt{file})\)**
  Returns the MD5 sum of the file contents read as bytes; note that the result will depend on the nature of the line endings used in the file, in contrast to normal \( \LaTeX \) behaviour. If the \(\texttt{file}\) is not found, nothing is returned with \textit{no error raised}.

- **l3kernel.filemoddate\((\texttt{file})\)**
  Returns the date/time of last modification of the \(\texttt{file}\) in the format
  \[\text{D:}\langle{\text{year}}\rangle\langle{\text{month}}\rangle\langle{\text{day}}\rangle\langle{\text{hour}}\rangle\langle{\text{minute}}\rangle\langle{\text{second}}\rangle\langle{\text{offset}}\rangle\]
  where the latter may be \(Z\) (UTC) or \(\langle{\text{plus-minus}}\rangle\langle{\text{hours}}\rangle\langle{\text{minutes}}\rangle\). If the \(\texttt{file}\) is not found, nothing is returned with \textit{no error raised}.

- **l3kernel.filesize\((\texttt{file})\)**
  Returns the size of the \(\texttt{file}\) in bytes. If the \(\texttt{file}\) is not found, nothing is returned with \textit{no error raised}.

- **l3kernel.resettimer()**
  Resets the timer used by \texttt{l3kernel.elapsedtime}.

- **l3kernel.shellescape\((\texttt{cmd})\)**
  Executes the \(\texttt{cmd}\) and prints to the log as for pdf\( \LaTeX \).

- **l3kernel.strcmp\((\texttt{str one}), (\texttt{str two})\)**
  Compares the two strings and returns 0 to \( \LaTeX \) if the two are identical.
Part XXXII

The l3unicode package: Unicode support functions

This module provides Unicode-specific functions along with loading data from a range of Unicode Consortium files. At present, it provides no public functions.
Part XXXIII

The \texttt{l3text} package: text processing

1 \texttt{l3text} documentation

This module deals with manipulation of (formatted) text; such material is comprised of a restricted set of token list content. The functions provided here concern conversion of textual content for example in case changing, generation of bookmarks and extraction to tags. All of the major functions operate by expansion. Begin-group and end-group tokens in the ⟨text⟩ are normalized and become \{ and \}, respectively.

1.1 Expanding text

\begin{verbatim}
\texttt{text\_expand:n \{⟨text⟩\}}
\end{verbatim}

Takes user input ⟨text⟩ and expands the content. Protected commands (typically formatting) are left in place, and no processing takes place of math mode material (as delimited by pairs given in \texttt{l_text_math_delims_tl} or as the argument to commands listed in \texttt{l_text_math_arg_tl}). Commands which are neither engine- nor \LaTeXX protected are expanded exhaustively. Any commands listed in \texttt{l_text_expand_exclude_tl}, \texttt{l_text_accents_tl} and \texttt{l_text_letterlike_tl} are excluded from expansion.

\begin{verbatim}
\texttt{text\_declare\_expand\_equivalent:Nn \texttt{text\_declare\_expand\_equivalent:cn}
\texttt{⟨cmd⟩ \{⟨replacement⟩⟩}}
\end{verbatim}

Declares that the ⟨replacement⟩ tokens should be used whenever the ⟨cmd⟩ (a single token) is encountered. The ⟨replacement⟩ tokens should be expandable.
\textlowercase:n * \textuppercase:n \tokens\} \textuppercase:nn \tokens\} \texttitlecase:n * \texttitlecasefirst:n * \textlowercase:nn * \textuppercase:nn * \texttitlecase:nn * \texttitlecasefirst:nn * 

1.2 Case changing

\textuppercase:n \tokens\} \textuppercase:nn \tokens\} \texttitlecase:n * \texttitlecasefirst:n * \textlowercase:nn * \textuppercase:nn * \texttitlecase:nn * \texttitlecasefirst:nn * 

Takes user input (text) first applies \textexpand, then transforms the case of character tokens as specified by the function name. The category code of letters are not changed by this process (at least where they can be represented by the engine as a single token: 8-bit engines may require active characters).

Upper- and lowercase have the obvious meanings. Titlecasing may be regarded informally as converting the first character of the (tokens) to uppercase and the rest to lowercase. However, the process is more complex than this as there are some situations where a single lowercase character maps to a special form, for example \textij in Dutch which becomes IJ. The \texttitlecasefirst variant does not attempt any case changing at all after the first letter has been processed.

Importantly, notice that these functions are intended for working with user text for typesetting. For case changing programmatic data see the l3str module and discussion there of \strlowercase:n, \struppercase:n and \strfoldcase:n.

Case changing does not take place within math mode material so for example

\textuppercase:n \text{Some-text-$y = mx + c$-with-{Braces}}

becomes

\text{SOME TEXT $y = mx + c$ WITH \{BRACES\}}

The arguments of commands listed in \textcaseexcludeargtl are excluded from case changing; the latter are entirely non-textual content (such as labels).

As is generally true for expl3, these functions are designed to work with Unicode input only. As such, UTF-8 input is assumed for all engines. When used with \Xpdf\TeX or \Luat\TeX a full range of Unicode transformations are enabled. Specifically, the standard mappings here follow those defined by the Unicode Consortium in UnicodeData.txt and SpecialCasing.txt. In the case of 8-bit engines, mappings are provided for characters which can be represented in output typeset using the \T1, \T2 and \LGR font encodings. Thus for example \text{ä} can be case-changed using \pdf\TeX. For \pdf\TeX only the ASCII range is covered as the engine treats input outside of this range as east Asian.

Language-sensitive conversions are enabled using the \language argument, and follow Unicode Consortium guidelines. Currently, the languages recognised for special handling are as follows.

- Azeri and Turkish (az and tr). The case pairs I/i-dotless and I-dot/i are activated for these languages. The combining dot mark is removed when lowering case I-dot and introduced when upper casing i-dotless.

- German (de-alt). An alternative mapping for German in which the lowercase \textEszett maps to a \textgroßes Eszett. Since there is a \T1 slot for the \textgroßes Eszett in \T1, this tailoring is available with \pdf\TeX as well as in the Unicode \TeX engines.

- Greek (el). Removes accents from Greek letters when upercasing: titlecasing leaves accents in place.

- Lithuanian (lt). The lowercase letters i and j should retain a dot above when the accents grave, acute or tilde are present. This is implemented for lowering of the relevant uppercase letters both when input as single Unicode codepoints and when using combining accents. The combining dot is removed when upercasing in these cases. Note that only the accents used in Lithuanian are covered: the behaviour of other accents are not modified.

- Dutch (nl). Capitalisation of iJ at the beginning of titlecased input produces IJ rather than Ij. The output retains two separate letters, thus this transformation is available using \pdf\TeX.

For titlecasing, note that there are two functions available. The function \textitlecase:n applies (broadly) upercasing to the first letter of the input, then lower-
1.3 Removing formatting from text

\text_purify:n * \text_purify:n \{(text)\}

Takes user input ⟨text⟩ and expands as described for \text_expand:n, then removes all functions from the resulting text. Math mode material (as delimited by pairs given in \l_text_math_delims_tl or as the argument to commands listed in \l_text_math_arg_tl) is left contained in a pair of \$ delimiters. Non-expandable functions present in the ⟨text⟩ must either have a defined equivalent (see \text_declare_purify_equivalent:Nn) or will be removed from the result. Implicit tokens are converted to their explicit equivalent.

\text_declare_purify_equivalent:Nn \text_declare_purify_equivalent:Nn ⟨cmd⟩ \{(replacement)\}
\text_declare_purify_equivalent:Nx

Declares that the ⟨replacement⟩ tokens should be used whenever the ⟨cmd⟩ (a single token) is encountered. The ⟨replacement⟩ tokens should be expandable.

1.4 Control variables

\l_text_accents_tl
Lists commands which represent accents, and which are left unchanged by expansion. (Defined only for the \LaTeX \texttt{2e} package.)

\l_text_letterlike_tl
Lists commands which represent letters; these are left unchanged by expansion. (Defined only for the \LaTeX \texttt{2e} package.)

\l_text_math_arg_tl
Lists commands present in the ⟨text⟩ where the argument of the command should be treated as math mode material. The treatment here is similar to \l_text_math_delims_tl but for a command rather than paired delimiters.

\l_text_math_delims_tl
Lists pairs of tokens which delimit (in-line) math mode content; such content may be excluded from processing.

\l_text_case_exclude_arg_tl
Lists commands which are excluded from case changing.

\l_text_expand_exclude_tl
Lists commands which are excluded from expansion.

\l_text_titlecase_check_letter_bool
Controls how the start of titlecasing is handled: when true, the first letter in text is considered. The standard setting is true.
Part XXXIV

The l3legacy package

Interfaces to legacy concepts

There are a small number of \TeX or \LaTeX\2ε concepts which are not used in expl3 code but which need to be manipulated when working as a \LaTeX\2ε package. To allow these to be integrated cleanly into expl3 code, a set of legacy interfaces are provided here.

\begin{verbatim}
\legacy_if:p:n * \legacy_if:nTF \langle name \rangle \{(true code)\} \{(false code)\}
\end{verbatim}

Tests if the \LaTeX\2ε/plain \TeX conditional (generated by \texttt{\newif}) if true or false and branches accordingly. The \langle name \rangle of the conditional should omit the leading if.
Part XXXV
The l3candidates package
Experimental additions to l3kernel

1 Important notice

This module provides a space in which functions can be added to l3kernel (expl3) while still being experimental.

As such, the functions here may not remain in their current form, or indeed at all, in l3kernel in the future.

In contrast to the material in l3experimental, the functions here are all small additions to the kernel. We encourage programmers to test them out and report back on the LaTeX-L mailing list.

Thus, if you intend to use any of these functions from the candidate module in a public package offered to others for productive use (e.g., being placed on CTAN) please consider the following points carefully:

• Be prepared that your public packages might require updating when such functions are being finalized.

• Consider informing us that you use a particular function in your public package, e.g., by discussing this on the LaTeX-L mailing list. This way it becomes easier to coordinate any updates necessary without issues for the users of your package.

• Discussing and understanding use cases for a particular addition or concept also helps to ensure that we provide the right interfaces in the final version so please give us feedback if you consider a certain candidate function useful (or not).

We only add functions in this space if we consider them being serious candidates for a final inclusion into the kernel. However, real use sometimes leads to better ideas, so functions from this module are not necessarily stable and we may have to adjust them!

2 Additions to l3box

2.1 Viewing part of a box

\box_clip:N \box_clip:c \box_gclip:N \box_gclip:c

Clips the ⟨box⟩ in the output so that only material inside the bounding box is displayed in the output. The updated ⟨box⟩ is an hbox, irrespective of the nature of the ⟨box⟩ before the clipping is applied.

These functions require the l3tpx3 native drivers: they do not work with the \LaTeX\ 2ε graphics drivers!

\TeXhackers note: Clipping is implemented by the driver, and as such the full content of the box is placed in the output file. Thus clipping does not remove any information from the raw output, and hidden material can therefore be viewed by direct examination of the file.

\iow_allow_break:
\ior_get_term:nN \ior_str_get_term:nN

New: 2019-03-23

\ior_get_term:nN \ior_str_get_term:nN (prompt) \token list variable

Function that reads one or more lines (until an equal number of left and right braces are found) from the terminal and stores the result locally in the \token list variable. Tokenization occurs as described for \ior_get:NN or \ior_str_get:NN, respectively. When the \prompt is empty, \TeX{} will wait for input without any other indication: typically the programmer will have provided a suitable text using e.g. \iow_term:n. Where the \prompt is given, it will appear in the terminal followed by an =, e.g.

\prompt=

\ior_shell_open:nN

New: 2019-05-08

\ior_shell_open:nN (stream) \{shell command\}

Opens the pseudo-file created by the output of the \shell command for reading using \stream as the control sequence for access. If the \stream was already open it is closed before the new operation begins. The \stream is available for access immediately and will remain allocated to \shell command until a \ior_close:n instruction is given or the \TeX run ends. If piped system calls are disabled an error is raised.

For details of handling of the \shell command, see \sys_get_shell:nnN(TF).

6 Additions to l3flag

\flag_raise_if_clear:n

New: 2018-04-02

\flag_raise_if_clear:n \{flag name\}

Ensures the \flag is raised by making its height at least 1, locally.

7 Additions to l3intarray

\intarray_gset_rand:Nnn \intarray_gset_rand:cn

\intarray_gset_rand:Nn \intarray_gset_rand:cn

New: 2018-05-05

\intarray_gset_rand:Nnn \intarray_gset_rand:cn \{integer array variable\} \{minimum\} \{maximum\}

Evaluates the integer expressions \minimum and \maximum then sets each entry (independently) of the \integer array variable to a pseudo-random number between the two (with bounds included). If the absolute value of either bound is bigger than $2^{30} - 1$, an error occurs. Entries are generated in the same way as repeated calls to \int_rand:nn or \int_rand:n respectively, in particular for the second function the \minimum is 1. Assignments are always global. This is not available in older versions of Xe\TeX.

7.1 Working with contents of integer arrays

\intarray_to_clist:N

New: 2018-05-04

\intarray_to_clist:N \{integer array\}

Converts the \integer array to integer denotations separated by commas. All tokens have category code other. If the \integer array has no entry the result is empty; otherwise the result has one fewer comma than the number of items.

8 Additions to \texttt{l3msg}

In very rare cases it may be necessary to produce errors in an expansion-only context. The functions in this section should only be used if there is no alternative approach using \texttt{\msg_error:nnnnnn} or other non-expandable commands from the previous section. Despite having a similar interface as non-expandable messages, expandable errors must be handled internally very differently from normal error messages, as none of the tools to print to the terminal or the log file are expandable. As a result, short-hands such as \texttt{\{ or \}} do not work, and messages must be very short (with default settings, they are truncated after approximately 50 characters). It is advisable to ensure that the message is understandable even when truncated, by putting the most important information up front. Another particularity of expandable messages is that they cannot be redirected or turned off by the user.

\begin{align*}
\texttt{\msg_expandable_error:nnnnnn} & \quad \texttt{\msg_expandable_error:nnnnnn} \langle \texttt{module} \rangle \langle \texttt{message} \rangle \langle \texttt{arg one} \rangle \langle \texttt{arg two} \rangle \langle \texttt{arg three} \rangle \langle \texttt{arg four} \rangle \\
\texttt{\msg_expandable_error:nnffff} & \quad \texttt{\msg_expandable_error:nnnnn} \langle \texttt{module} \rangle \langle \texttt{message} \rangle \langle \texttt{arg one} \rangle \langle \texttt{arg two} \rangle \langle \texttt{arg three} \rangle \langle \texttt{arg four} \rangle \\
\texttt{\msg_expandable_error:nnnnn} & \quad \texttt{\msg_expandable_error:nnnn} \langle \texttt{module} \rangle \langle \texttt{message} \rangle \langle \texttt{arg one} \rangle \langle \texttt{arg two} \rangle \langle \texttt{arg three} \rangle \langle \texttt{arg four} \rangle \\
\texttt{\msg_expandable_error:nnnnn} & \quad \texttt{\msg_expandable_error:nnxx} \langle \texttt{module} \rangle \langle \texttt{message} \rangle \langle \texttt{arg one} \rangle \langle \texttt{arg two} \rangle \langle \texttt{arg three} \rangle \langle \texttt{arg four} \rangle \\
\texttt{\msg_expandable_error:nnnnn} & \quad \texttt{\msg_expandable_error:nnn} \langle \texttt{module} \rangle \langle \texttt{message} \rangle \langle \texttt{arg one} \rangle \langle \texttt{arg two} \rangle \langle \texttt{arg three} \rangle \langle \texttt{arg four} \rangle \\
\texttt{\msg_expandable_error:nnn} & \quad \texttt{\msg_expandable_error:nnx} \langle \texttt{module} \rangle \langle \texttt{message} \rangle \langle \texttt{arg one} \rangle \langle \texttt{arg two} \rangle \langle \texttt{arg three} \rangle \langle \texttt{arg four} \rangle \\
\texttt{\msg_expandable_error:nn} & \quad \texttt{\msg_expandable_error:n} \langle \texttt{module} \rangle \langle \texttt{message} \rangle \langle \texttt{arg one} \rangle \langle \texttt{arg two} \rangle \langle \texttt{arg three} \rangle \langle \texttt{arg four} \rangle
\end{align*}

Issues an “Undefined error” message from \TeX itself using the undefined control sequence \texttt{\texttt{\::error}} then prints “\langle \texttt{module} \rangle: “\langle \texttt{error message} \rangle”, which should be short. With default settings, anything beyond approximately 60 characters long (or bytes in some engines) is cropped. A leading space might be removed as well.

\begin{align*}
\texttt{\msg_show_eval:Nn} & \quad \texttt{\msg_log_eval:Nn} \\
\texttt{\msg_show:nnnnnn} & \quad \texttt{\msg_show:nnxxxx} \\
\texttt{\msg_show:nnnnn} & \quad \texttt{\msg_show:nnnn} \\
\texttt{\msg_show:nnnn} & \quad \texttt{\msg_show:nnxx} \\
\texttt{\msg_show:nn} & \quad \texttt{\msg_show:nn} \\
\texttt{\msg_show_eval:Nn} & \quad \texttt{\msg_log_eval:Nn}
\end{align*}

\begin{align*}
\texttt{\msg_show:nnnnnn} & \quad \texttt{\msg_show:nnnnnn} \langle \texttt{module} \rangle \langle \texttt{message} \rangle \langle \texttt{arg one} \rangle \langle \texttt{arg two} \rangle \langle \texttt{arg three} \rangle \langle \texttt{arg four} \rangle \\
\texttt{\msg_show:nnnnn} & \quad \texttt{\msg_show:nnnnn} \langle \texttt{module} \rangle \langle \texttt{message} \rangle \langle \texttt{arg one} \rangle \langle \texttt{arg two} \rangle \langle \texttt{arg three} \rangle \langle \texttt{arg four} \rangle \\
\texttt{\msg_show:nnxxx} & \quad \texttt{\msg_show:nnxxx} \langle \texttt{module} \rangle \langle \texttt{message} \rangle \langle \texttt{arg one} \rangle \langle \texttt{arg two} \rangle \langle \texttt{arg three} \rangle \langle \texttt{arg four} \rangle \\
\texttt{\msg_show:nnxx} & \quad \texttt{\msg_show:nnxx} \langle \texttt{module} \rangle \langle \texttt{message} \rangle \langle \texttt{arg one} \rangle \langle \texttt{arg two} \rangle \langle \texttt{arg three} \rangle \langle \texttt{arg four} \rangle \\
\texttt{\msg_show:nnn} & \quad \texttt{\msg_show:nnn} \langle \texttt{module} \rangle \langle \texttt{message} \rangle \langle \texttt{arg one} \rangle \langle \texttt{arg two} \rangle \langle \texttt{arg three} \rangle \langle \texttt{arg four} \rangle \\
\texttt{\msg_show:nn} & \quad \texttt{\msg_show:nn} \langle \texttt{module} \rangle \langle \texttt{message} \rangle \langle \texttt{arg one} \rangle \langle \texttt{arg two} \rangle \langle \texttt{arg three} \rangle \langle \texttt{arg four} \rangle
\end{align*}

Shows or logs the \langle \texttt{expression} \rangle (turned into a string), an equal sign, and the result of applying the \langle \texttt{function} \rangle to the \langle \texttt{expression} \rangle (with \texttt{f}-expansion). For instance, if the \langle \texttt{function} \rangle is \texttt{\int_eval:n} and the \langle \texttt{expression} \rangle is 1+2 then this logs > 1+2=3.

\begin{align*}
\texttt{\msg_show:nnnnn} & \quad \texttt{\msg_show:nnnnnn} \langle \texttt{module} \rangle \langle \texttt{message} \rangle \langle \texttt{arg one} \rangle \langle \texttt{arg two} \rangle \langle \texttt{arg three} \rangle \langle \texttt{arg four} \rangle
\end{align*}

Issues \langle \texttt{module} \rangle information \langle \texttt{message} \rangle, passing \langle \texttt{arg one} \rangle to \langle \texttt{arg four} \rangle to the text-creating functions. The information text is shown on the terminal and the \TeX run is interrupted in a manner similar to \texttt{\tl_show:n}. This is used in conjunction with \texttt{\msg_show_item:n} and similar functions to print complex variable contents completely. If the formatted text does not contain >~ at the start of a line, an additional line >~ will be put at the end. In addition, a final period is added if not present.
Used in the text of messages for \texttt{msg\_show:nnxxx} to show or log a list of items or key–value pairs. The one-argument functions are used for sequences, clist or token lists and the others for property lists. These functions turn their arguments to strings.

9 Additions to \texttt{l3prg}

ewcommand{\bool_set_inverse}{\langle boolean \rangle}

\bool_set_inverse \langle boolean \rangle

Toggles the \langle boolean \rangle from \texttt{true} to \texttt{false} and conversely: sets it to the inverse of its current value.

\newcommand{\bool_case_true}{\langle boolean expression cases \rangle}
\newcommand{\bool_case_false}{\langle boolean expression cases \rangle}

\bool_case_true

\begin{verbatim}
{ \dim_compare_p:n { \l__mypkg_wd_dim <= 10pt } }
{ Fits }
{ \int_compare_p:n { \l__mypkg_total_int >= 10 } }
{ Many }
{ \l__mypkg_special_bool }
{ Special }

{ No idea! }
\end{verbatim}

leaves “Fits” or “Many” or “Special” or “No idea!” in the input stream, in a way similar to some other language’s “if \ldots elseif \ldots elseif \ldots else \ldots”.
10 Additions to \texttt{l3prop}

\begin{verbatim}
\prop_rand_key_value:N \prop_rand_key_value:c
\end{verbatim}

Selects a pseudo-random key–value pair from the \texttt{property list} and returns \texttt{\{key\}} and \texttt{\{value\}}. If the \texttt{property list} is empty the result is empty. This is not available in older versions of \texttt{Xe\LaTeX}.

\textbf{\TeX hackers note:} The result is returned within the \texttt{\unexpanded} primitive \texttt{\exp_not:n}, which means that the \texttt{\value} does not expand further when appearing in an \texttt{x}-type argument expansion.

11 Additions to \texttt{l3seq}

\begin{verbatim}
\seq_mapthread_function:NNN \seq_mapthread_function:NNN (\seq_{1}) (\seq_{2}) (function)
\end{verbatim}

Applies \texttt{(function)} to every pair of items \texttt{\seq_{1}-item}–\texttt{\seq_{2}-item} from the two sequences, returning items from both sequences from left to right. The \texttt{(function)} receives two \texttt{n}-type arguments for each iteration. The mapping terminates when the end of either sequence is reached (\textit{i.e.} whichever sequence has fewer items determines how many iterations occur).

\begin{verbatim}
\seq_set_filter:NNn \seq_gset_filter:NNn \seq_set_map:NNn \seq_gset_map:NNn
\end{verbatim}

\textbf{\TeX hackers note:} Contrarily to other mapping functions, \texttt{\seq_map_break:} cannot be used in this function, and would lead to low-level \TeX errors.
\seq_set_from_function:NnN \seq_gset_from_function:NnN
\seq_set_from_function:NnN \seq_gset_from_function:NnN
\seq_set_from_function:NnN \seq_gset_from_function:NnN

\seq_indexed_map_function:NN \seq_indexed_map_function:NN \seq_indexed_map_function:NN
\seq_indexed_map_function:NN
\seq_indexed_map_function:NN
\seq_indexed_map_function:NN

\seq_set_from_inline_x:Nnn \seq_set_from_inline_x:Nnn \seq_set_from_inline_x:Nnn
\seq_set_from_inline_x:Nnn \seq_gset_from_inline_x:Nnn \seq_gset_from_inline_x:Nnn

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\seq_set_from_function:NnN</td>
<td>Sets the \texttt{(seq)} equal to a sequence whose items are obtained by x-expanding \texttt{(loop code)} and \texttt{(function)}. This expansion must result in successive calls to the \texttt{(function)} with no nonexpandable tokens in between. More precisely the \texttt{(function)} is replaced by a wrapper function that inserts the appropriate separators between items in the sequence. The \texttt{(loop code)} must be expandable; it can be for example \texttt{\tl_map_function:NN (tl var)} or \texttt{\clist_map_function:nN {clist}} or \texttt{\int_step_function:nnnN {(initial value)} {(step)} {(final value)}}.</td>
</tr>
<tr>
<td>\seq_set_from_inline_x:Nnn</td>
<td>Sets the \texttt{(seq)} equal to a sequence whose items are obtained by x-expanding \texttt{(loop code)} applied to a \texttt{(function)} derived from the \texttt{(inline code)}. A \texttt{(function)} is defined, that takes one argument, x-expands the \texttt{(inline code)} with that argument as \texttt{#1}, then adds appropriate separators to turn the result into an item of the sequence. The x-expansion of \texttt{(loop code)} \texttt{(function)} must result in successive calls to the \texttt{(function)} with no nonexpandable tokens in between. The \texttt{(loop code)} must be expandable; it can be for example \texttt{\tl_map_function:NN (tl var)} or \texttt{\clist_map_function:nN {clist}} or \texttt{\int_step_function:nnnN {(initial value)} {(step)} {(final value)}}, but not the analogous “inline” mappings.</td>
</tr>
<tr>
<td>\seq_indexed_map_function:NN</td>
<td>Applies \texttt{(function)} to every entry in the \texttt{(sequence variable)}. The \texttt{(function)} should have signature \texttt{:nn}. It receives two arguments for each iteration: the \texttt{(index)} (namely \texttt{1} for the first entry, then \texttt{2} and so on) and the \texttt{(item)}.</td>
</tr>
<tr>
<td>\seq_indexed_map_inline:Nn</td>
<td>Applies \texttt{(inline function)} to every entry in the \texttt{(sequence variable)}. The \texttt{(inline function)} should consist of code which receives the \texttt{(index)} (namely \texttt{1} for the first entry, then \texttt{2} and so on) as \texttt{#1} and the \texttt{(item)} as \texttt{#2}.</td>
</tr>
</tbody>
</table>
12 Additions to \texttt{l3sys}

\c_sys_engine_version_str

The version string of the current engine, in the same form as given in the banner issued when running a job. For \texttt{pdf\TeX} and \texttt{Lua\TeX} this is of the form

\langle \text{major}.\langle \text{minor}.\langle \text{revision}\rangle \rangle \rangle

For \texttt{Xe\TeX}, the form is

\langle \text{major}.\langle \text{minor}\rangle \rangle

For \texttt{p\TeX} and \texttt{up\TeX}, only releases since \TeX\ Live 2018 make the data available, and the form is more complex, as it comprises the \texttt{p\TeX} version, the \texttt{up\TeX} version and the e-\texttt{p\TeX} version.

\texttt{p\langle \text{major}.\langle \text{revision}\rangle \text{u} \langle \text{major}.\langle \text{minor}\rangle \text{e}\langle \text{p\TeX}\rangle}}

where the \texttt{u} part is only present for \texttt{up\TeX}.

\sys_if_rand_exist_p: *
\sys_if_rand_exist:TF *

Tests if the engine has a pseudo-random number generator. Currently this is the case in \texttt{pdf\TeX}, \texttt{Lua\TeX}, \texttt{p\TeX}, \texttt{up\TeX} and recent releases of \texttt{Xe\TeX}.
Leaves in the input stream the items from the (start index) to the (end index) inclusive, using the same indexing as \tl_range:nnn. Spaces are ignored. Regardless of whether items appear with or without braces in the (token list), the \tl_range_braced:nnn function wraps each item in braces, while \tl_range_unbraced:nnn does not (overall it removes an outer set of braces). For instance,

\begin{verbatim}
 \iow_term:x { \tl_range_braced:nnn { abcd-{e{}}f } { 2 } { 5 } }
 \iow_term:x { \tl_range_braced:nnn { abcd-{e{}}f } { -4 } { -1 } }
 \iow_term:x { \tl_range_braced:nnn { abcd-{e{}}f } { -2 } { -1 } }
 \iow_term:x { \tl_range_braced:nnn { abcd-{e{}}f } { 0 } { -1 } }
\end{verbatim}

prints \{b}{c}{d}{e{}}, \{c}{d}{e{}}{f}, {e{}}{f}, and an empty line to the terminal, while

\begin{verbatim}
 \iow_term:x { \tl_range_unbraced:nnn { abcd-{e{}}f } { 2 } { 5 } }
 \iow_term:x { \tl_range_unbraced:nnn { abcd-{e{}}f } { -4 } { -1 } }
 \iow_term:x { \tl_range_unbraced:nnn { abcd-{e{}}f } { -2 } { -1 } }
 \iow_term:x { \tl_range_unbraced:nnn { abcd-{e{}}f } { 0 } { -1 } }
\end{verbatim}

prints bcde{}, cde{}f, e{}f, and an empty line to the terminal. Because braces are removed, the result of \tl_range_unbraced:nnn may have a different number of items as for \tl_range:nnn or \tl_range_braced:nnn. In cases where preserving spaces is important, consider the slower function \tl_range:nnn.

\textbf{TexHackers note:} The result is returned within the \texttt{\exp_not:n} primitive, which means that the (item) does not expand further when appearing in an x-type argument expansion.

\begin{verbatim}
\tl_build_begin:N \tl_build_gbegin:N \tl_build_end:N \tl_build_gend:N \tl_build_clear:N \tl_build_gclear:N
\end{verbatim}

Clears the (tl var) and sets it up to support other \tl_build_... functions, which allow accumulating large numbers of tokens piece by piece much more efficiently than standard l3tl functions. Until \tl_build_end:N \{tl var\} is called, applying any function from l3tl other than \tl_build_... will lead to incorrect results. The begin and gbegin functions must be used for local and global \{tl var\} respectively.

Clears the (tl var) and sets it up to support other \tl_build_... functions. The clear and gclear functions must be used for local and global \{tl var\} respectively.

14 Additions to \texttt{l3token}

Token list containing one character with category code 13, ("active"), and character code 32 (space).

\char_to_utfviii_bytes:n {\langle codepoint \rangle}

Converts the (Unicode) \texttt{\langle codepoint \rangle} to UTF-8 bytes. The expansion of this function comprises four brace groups, each of which will contain a hexadecimal value: the appropriate byte. As UTF-8 is a variable-length, one or more of the groups may be empty: the bytes read in the logical order, such that a two-byte codepoint will have groups \#1 and \#2 filled and \#3 and \#4 empty.

\char_to_nfd:N {\langle char \rangle}

Converts the \texttt{\langle char \rangle} to the Unicode Normalization Form Canonical Decomposition. The category code of the generated character is the same as the \texttt{\langle char \rangle}. With 8-bit engines, no change is made to the character.

269
Collects and removes tokens from the input stream until finding a token that does not match the \(\text{⟨test token⟩}\) (as defined by the test \token_if_eq_catcode:NNTF or \token_if_eq_charcode:NNTF or \token_if_eq_meaning:NNTF). The collected tokens are passed to the \(\langle\text{inline code}⟩\) as #1. When begin-group or end-group tokens (usually \{ or \}) are collected they are replaced by implicit \c_group_begin_token and \c_group_end_token, and when spaces (including \c_space_token) are collected they are replaced by explicit spaces.

For example the following code prints “Hello” to the terminal and leave “, world!” in the input stream.

\peek_catcode_collect_inline:Nn \peek_catcode_collect_inline:Nn \peek_catcode_collect_inline:Nn \peek_charcode_collect_inline:Nn \peek_charcode_collect_inline:Nn \peek_charcode_collect_inline:Nn \peek_meaning_collect_inline:Nn \peek_meaning_collect_inline:Nn A \{ \iow_term:n {#1} \} Hello,~world!

Another example is that the following code tests if the next token is \*, ignoring intervening spaces, but putting them back using #1 if there is no \*.

\peek_remove_spaces:n \peek_remove_spaces:n \peek_remove_spaces:n

\peek_meaning_collect_inline:Nn \c_space_token \{ \peek_charcode:NTF * \{ star \} \{ no-star #1 \} \}
# Index

The italic numbers denote the pages where the corresponding entry is described, numbers underlined point to the definition, all others indicate the places where it is used.
